

Oceanic Tracers

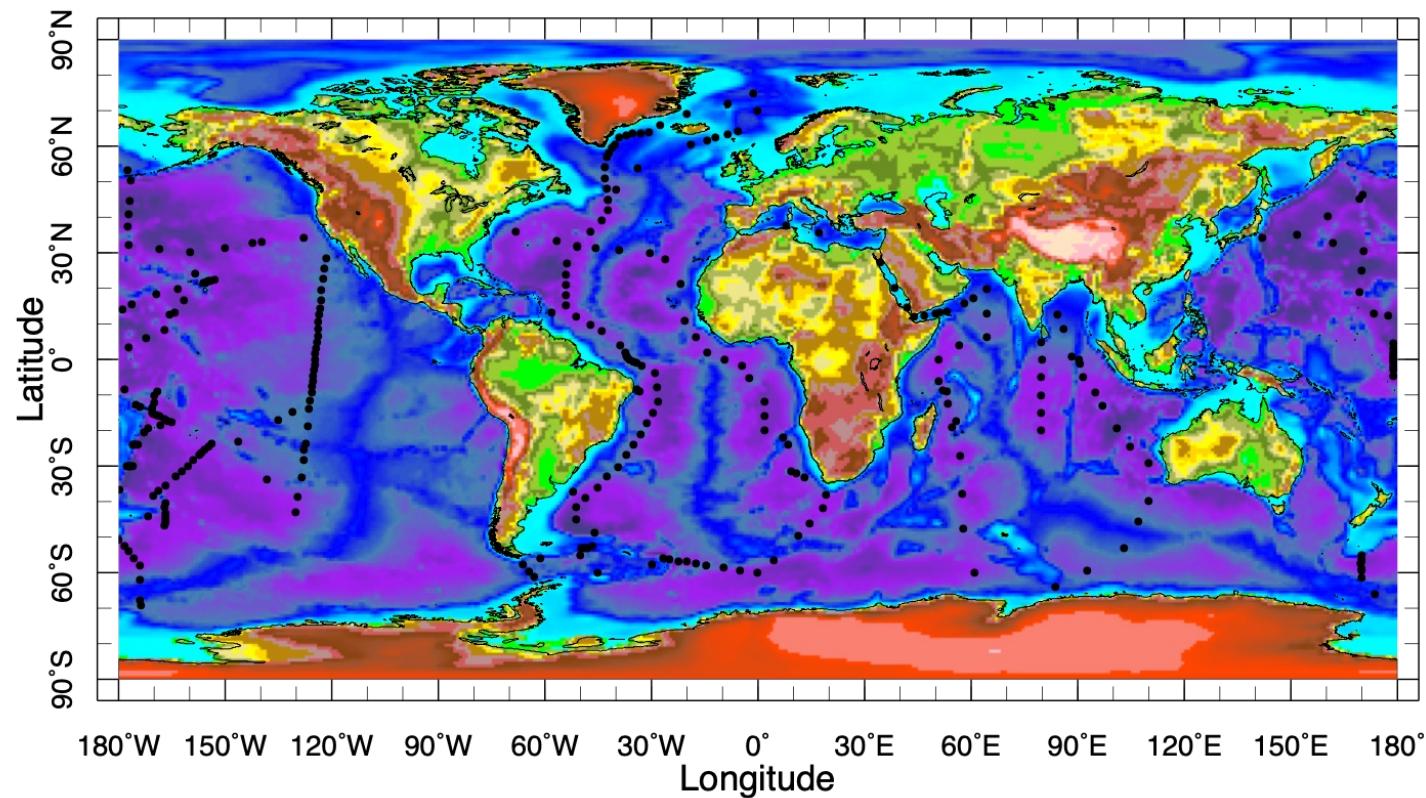

- Classes of oceanic tracers
- Global ocean surveys
- Water-mass mixing calculations
- Quasi-conservative geochemical tracers
- NO, PO, and PO_4^*
- Anthropogenic transient and deliberate Tracers
- CFCs, SF_6

Type	Use
Natural - Stable	
O ₂	Water mass analysis, non-conservative
PO ₄ , NO ₃ , SiO ₂	Nutrients high in Pacific water, low in Atlantic Water
NO, PO, PO ₄ *	Water mass analysis, quasi-conservative
¹⁸ O, ⁴ He, Ne	Identify and quantify glacial ice (⁴ He & Ne high, ¹⁸ O low in glacial ice)
³ He	Circulation of CDW onto Antarctic continental shelves (³ He high in CDW); gas exchange
Natural - Radioactive	
¹⁴ C	Large scale deep water circulation and mixing; ocean CO ₂ uptake on century to millennial time scales
Anthropogenic - Transient	
CFC-11, CFC-12, CFC-113, CCl ₄ , SF ₆	Identify most recently formed water; circulation pathways, water mass ages, water mass formation rates, estimation of anthropogenic CO ₂ uptake
³ H	Same as trace gases above, but weak signal in S.H.
Bomb ¹⁴ C	Ocean uptake of anthropogenic CO ₂
Anthropogenic - Deliberate	
SF ₆ , CF ₃ SF ₅	Mixing, circulation, and gas exchange

Mixing of Two Water Masses

- Plot two stable **conservative** tracers for each water mass on an X-Y plot (e.g., T, S)
- Link points with a linear “mixing line”
- Water samples with compositions falling along the mixing line are composed of mixtures of the two water masses

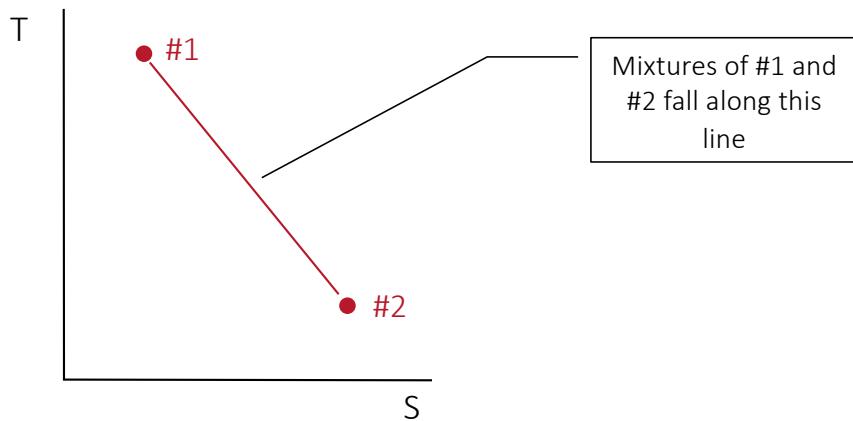

Water mass mixing definitions

- Assume: conservation of mass, heat, salt
- Definitions:
 - C_i = concentration of some stable conservative property in water mass “i” (end-member concentration)
 - C_{mix} = concentration of some stable **conservative** property in a water mixture
 - f_i = fraction of the water mixture that is from water mass “i”
 - $f_{mix} = 1.0 = f_1 + f_2 + \dots + f_i$ (mass balance equation)

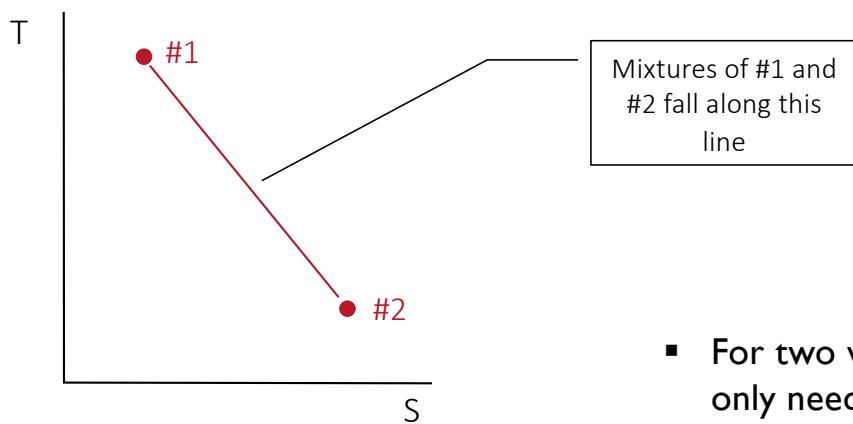

Mixing of Two Water Masses

- Plot two stable **conservative** tracers for each water mass on an X-Y plot (e.g., T, S)
- Link points with a linear “mixing line”
- Water samples with compositions falling along the mixing line are composed of mixtures of the two water masses

Mixing of Two Water Masses

- Plot two stable **conservative** tracers for each water mass on an X-Y plot (e.g., T, S)
- Link points with a linear “mixing line”
- Water samples with compositions falling along the mixing line are composed of mixtures of the two water masses

$$1 = f_1 + f_2 \quad (1)$$

$$C_{mix} = f_1 C_1 + f_2 C_2 \quad (2)$$

Combining:

$$f_1 = \frac{C_{mix} - C_2}{C_1 - C_2}$$

- For two water masses: only need **T** or **S**

Mixing of Four Water Masses

We need four equations with four variables. For example:

$$l = f_1 + f_2 + f_3 + f_4$$

$$T_{\text{mix}} = f_1 T_1 + f_2 T_2 + f_3 T_3 + f_4 T_4$$

$$S_{\text{mix}} = f_1 S_1 + f_2 S_2 + f_3 S_3 + f_4 S_4$$

$$\sigma_{\text{mix}} = f_1 \sigma_1 + f_2 \sigma_2 + f_3 \sigma_3 + f_4 \sigma_4$$

Thus, we need three stable, conservative tracers:

T_i = temperature of water mass “i”

T_{mix} = temperature of a water mixture

S_i = salinity of water mass “i”

S_{mix} = salinity of a water mixture

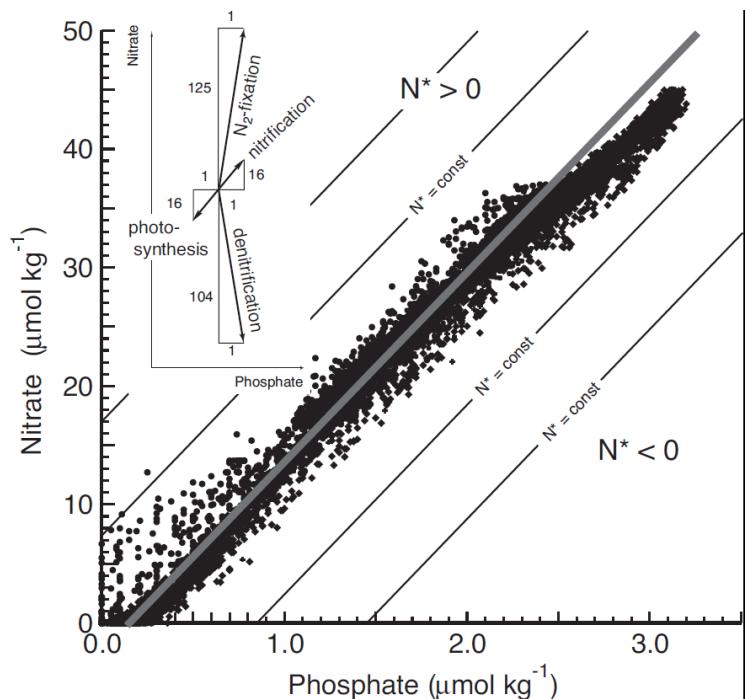

σ_i = [?] of water mass “i”

σ_{mix} = [?] of a water mixture

- What to use for the third conservative tracer?

Quasi-conservative tracers (from Export lecture)

N^* is a tracer for denitrification in the ocean

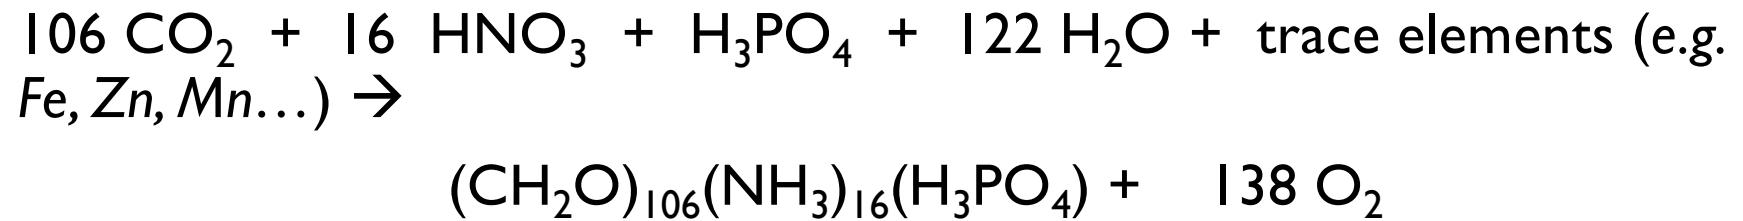

N^* is defined as

$$N^* = [\text{NO}_3] - 16 \times [\text{PO}_4] + 2.9$$

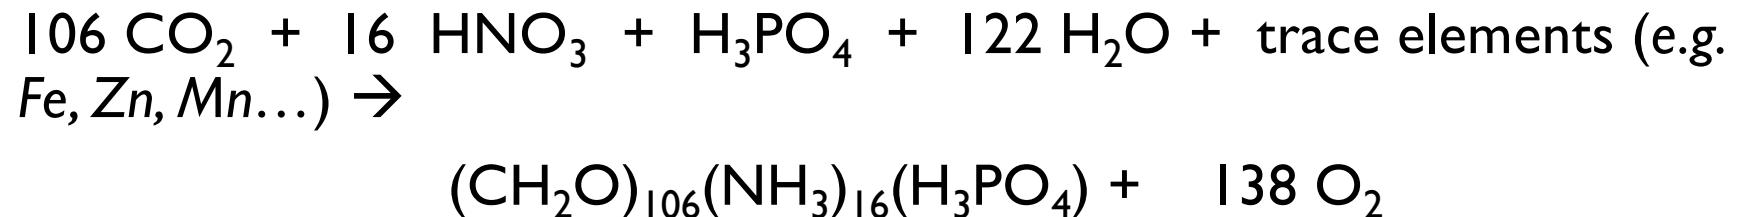

The solid line shows the linear equation with $\text{N:P} = 16$

Values to the right have negative N^* (denitrification)
to the left have positive N^* (nitrogen fixation)

“NO” – A Quasi-Conservative Water Mass Tracer

“NO” – A Quasi-Conservative Water Mass Tracer

$$\Delta \text{O}_2 / \Delta \text{N} = -138 / 16 = -8.6$$

Thus, during the oxidation of organic matter:

For each mole of NO_3^- released to a water mass,
~9 moles of O_2 is removed

Broecker (1974): “NO” $\equiv 9[\text{NO}_3^-] + [\text{O}_2]$

“PO” $\equiv 135[\text{PO}_4^{3-}] + [\text{O}_2]$

“NO”, A CONSERVATIVE WATER-MASS TRACER*

WALLACE S. BROECKER
*Lamont-Doherty Geological Observatory and Department of Geology,
Columbia University, Palisades, N.Y. (USA)*

Received February 20, 1974
Revised version received June 13, 1974

A composite property, $9\text{NO}_3 + \text{O}_2$, is proposed as a conservative water-mass tracer. The coefficient 9 is chosen so that the increase in “NO” resulting from nitrate introduction during respiration just balances the consumption of dissolved oxygen gas. Because of the pronounced difference in the preformed nitrate content of deep water produced at the northern and southern ends of the Atlantic Ocean “NO” provides an independent means of disentangling the degree of mixing of various water types in the deep sea. Evidence based on data obtained during the Atlantic Geosecs program is presented to demonstrate the sensitivity and reliability of this conservative tracer.

Conservative Behavior of “NO”

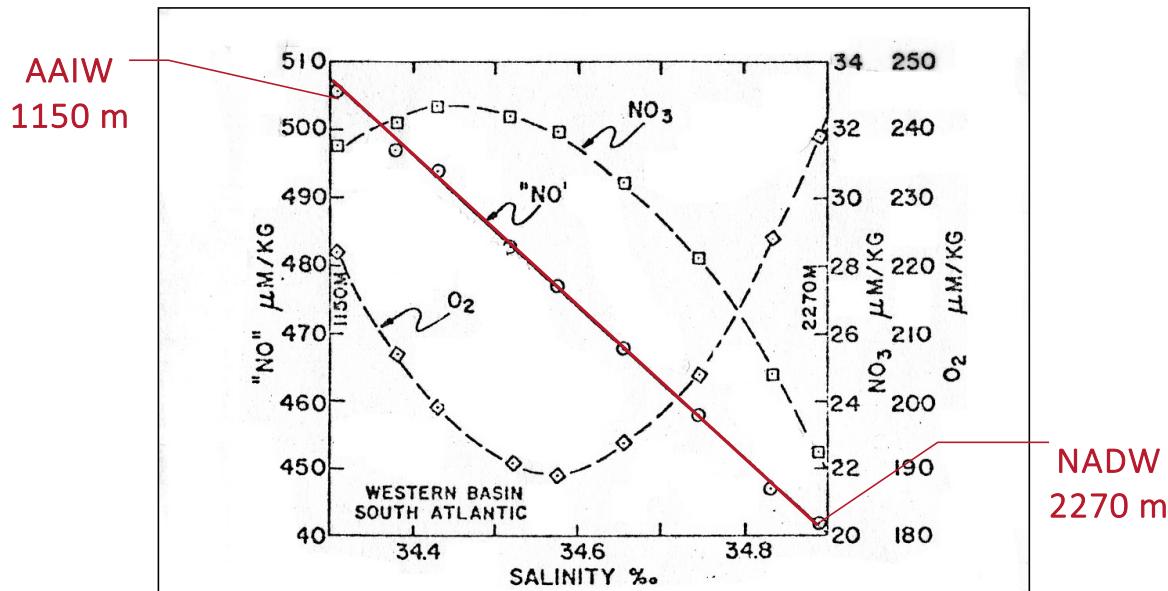

Fig. 5. “NO”, NO_3 , and O_2 versus salinity at Atlantic Geosecs station 60 in the western basin of the South Atlantic between the core of the AAIW (1150 m) and the top of the NADW (2270 m). The excess NO_3 content is just balanced by the O_2 deficiency yielding a straight line relationship between salinity and “NO”.

Mixing of Four Water Masses

We need four equations with four variables. For example:

$$I = f_1 + f_2 + f_3 + f_4$$

$$T_{\text{mix}} = f_1 T_1 + f_2 T_2 + f_3 T_3 + f_4 T_4$$

$$S_{\text{mix}} = f_1 S_1 + f_2 S_2 + f_3 S_3 + f_4 S_4$$

$$\text{NO}_{\text{mix}} = f_1 \text{NO}_1 + f_2 \text{NO}_2 + f_3 \text{NO}_3 + f_4 \text{NO}_4$$

Thus, we need three stable, conservative tracers:

T_i = temperature of water mass “i”

T_{mix} = temperature of a water mixture

S_i = salinity of water mass “i”

S_{mix} = salinity of a water mixture

NO_i = NO of water mass “i”

NO_{mix} = NO of a water mixture

PO_4^* – Another Quasi-Conservative Water Mass Tracer

RADIOCARBON DECAY AND OXYGEN UTILIZATION IN THE DEEP ATLANTIC OCEAN

Wallace S. Broecker, Sean Blanton,
and William M. Smetacek, Jr.

Lamont-Doherty Geological Observatory of
Columbia University, Palisades, New York

Görel Ostlund

Rosenstiel School of Marine and Atmospheric
Sciences, University of Miami, Miami, Florida

Abstract. A parameter based on the sum of the concentrations of PO_4 and O_2 (divided by the Redfield coefficient $\Delta\text{O}_2/\Delta\text{PO}_4$) is used to separate the contributions of the northern and southern components to deep waters in the Atlantic. This separation allows the amount of radiocarbon lost by radiodecay and the amount of oxygen lost to respiration during respiration in the deep Atlantic to be calculated. Maps of these quantities reveal strong west to east gradients and south to north gradients consistent with ventilation along the western boundary from both ends of the ocean coupled with mixing outward from the boundary. The O_2 and ^{14}C deficiencies are highly correlated, suggesting an O_2 utilization rate of $12 \mu\text{mol/kg}$ per century. The apparent mean isolation time of water in the deep Atlantic is about 200 years.

INTRODUCTION

Both the distribution of dissolved oxygen and that of radiocarbon in the deep Atlantic are strongly influenced by the mixing between the northern and southern components of deep water. Hence if the extent of changes in O_2 content caused by respiration and of changes in the radiocarbon to carbon ratio caused by radioactive decay are to be isolated, then a means must be found to accurately define the relative contribution of these two sources to any given water sample. As was shown by Broecker [1979] and by

Broecker et al. [1985], a promising means to do this is through the use of a PO_4-O_2 based quasi-conservative parameter. Broecker [1974] initially suggested a parameter called "PO" based on the sum of the O_2 concentration and a Redfield ratio multiple (i.e., a sum of the PO_4 concentration). In this paper we employ a modification of "PO" which we believe yields a more accurate separation of the contributors. We apply this new separation procedure to the expansion of the Geochemical Ocean Sections (GEOSECS) data set for the deep Atlantic made available by the Transient Tracers in the Ocean (TTO), Tropical Atlantic Survey (TAS) and South Atlantic Ventilation Experiment (SAVE).

COMPONENT CHARACTERIZATION

We base our separation of the northern and southern component contributions to deep waters (i.e., $>2000 \text{ m}$) on the addition of a parameter we designate as PO_4^* . It is related to the measured PO_4 and O_2 concentrations as follows:

$$\text{PO}_4^* = \text{PO}_4 + \frac{\text{O}_2}{175} - 1.95 \mu\text{mol/kg}$$

The constant term (1.95) is introduced in order to bring the PO_4^* values into the range of measured PO_4 contents in the deep sea. The revised Redfield ratio (175) relating O_2 consumption to PO_4 production during respiration is the global average proposed by Broecker et al. [1985]. It is the average analysis of water column chemical data from six different regions in the ocean deemed suitable for this type of analysis. As is summarized in Table 1, despite the

Broecker (1985):

$$\Delta\text{O}_2 / \Delta\text{PO}_4 = -175 / 1 = -175$$

Thus, during the oxidation of organic matter:

For each mole of PO_4^- released to a water mass, ~ 175 moles of O_2 is removed

Broecker et al. (1991):

$$[\text{PO}_4^*] \equiv [\text{PO}_4^-] + \frac{[\text{O}_2]}{175} - 1.95 \mu\text{mol/kg}$$

Separating NADW from AABW

Salinity (S) is conservative, but 4 water masses that combine to form NADW have different S.

PO_4^* is nearly uniform within AABW and within the four components of NADW (*Broecker et al., 1998*):

AABW: $1.95 \pm 0.07 \mu\text{mol kg}^{-1}$

NADW: $0.73 \pm 0.07 \mu\text{mol kg}^{-1}$

Fraction of NADW is:

$$f_{\text{NADW}} = \frac{1.95 - [\text{PO}_4^*]}{1.95 - 0.73}$$

Transient Tracers

- Usually anthropogenic compounds with time-varying sources (or sinks)
 - CFCs, SF₆, ¹⁴C, ³H
- They enter the surface waters of the ocean either via gas exchange (e.g., CFCs, SF₆, ¹⁴C) or water vapor exchange (³H)
- Transient tracers allow:
 - Penetration of surface perturbations into the interior of the oceans to be visualized.
 - Delineation of pathways that newly formed subsurface water follows after leaving the surface.
 - Investigation of ocean circulation and mixing, and validation/calibration of GCMs.
 - Determination of water mass formation rates
 - Estimation of anthropogenic CO₂ inventory in the ocean

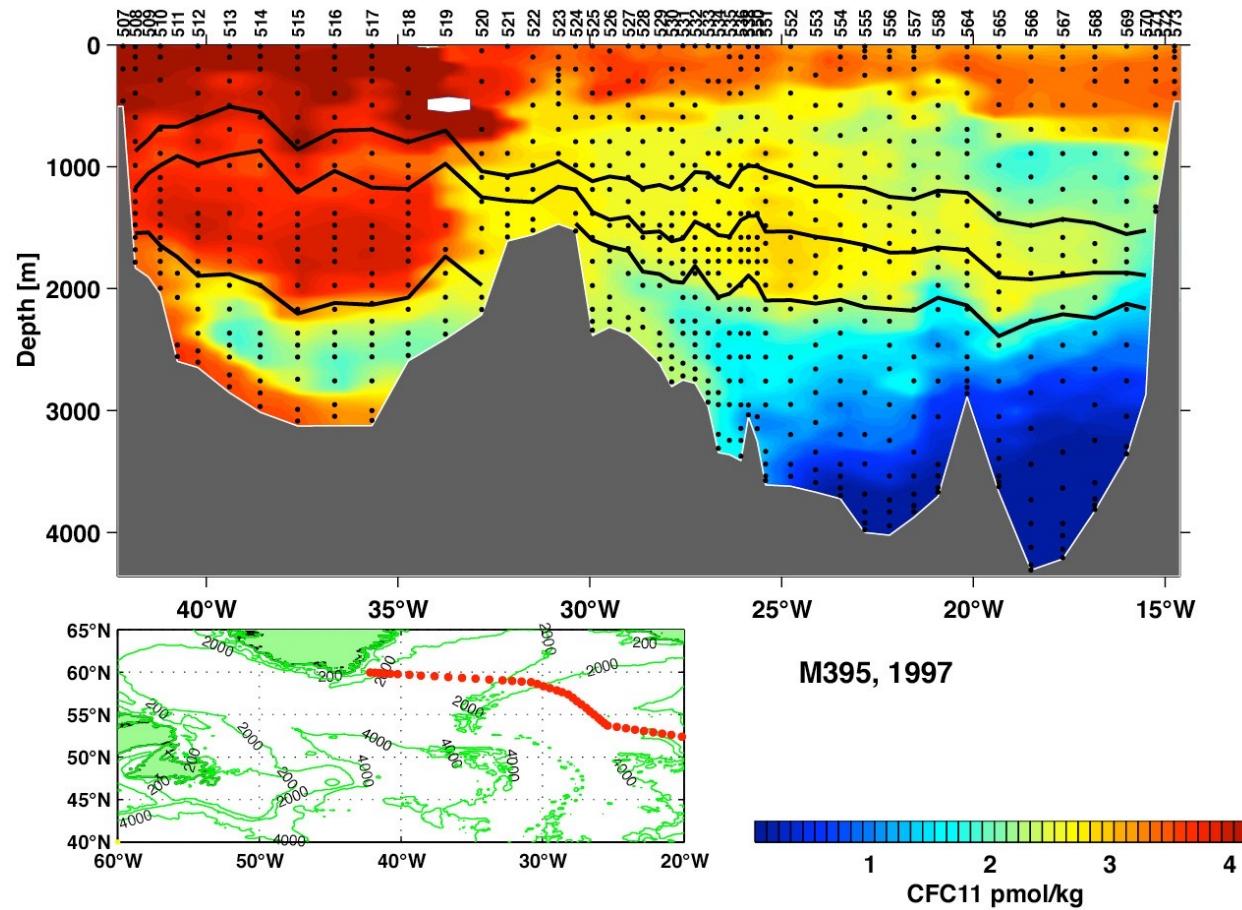

Northern Hemisphere Atmospheric Concentrations: CFCs, CCl_4 and SF_6

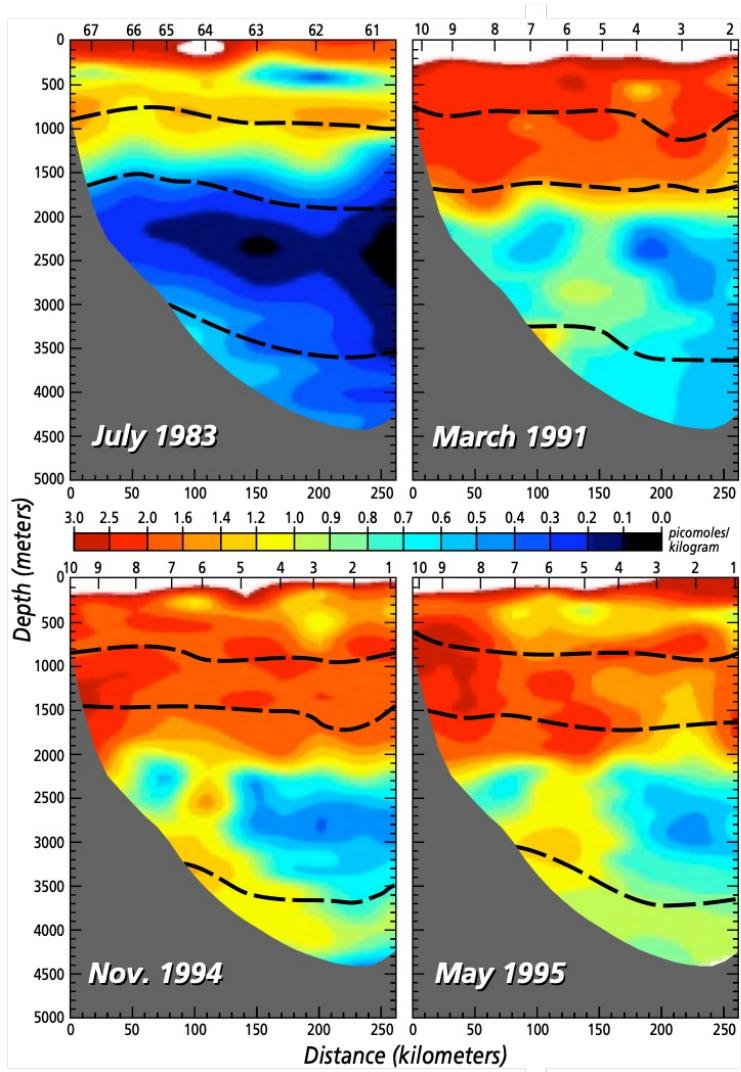

Solubilities of CFCs & SF₆

- Strong function of temperature
- Increases as temperature decreases
- Ranges by a factor of about 3.5 between 0 and 25°C
- Weaker function of salinity
- Decreases as salinity increases
- Varies by 50% between salinity of 0 and 35
- Solubilities are well known ($\pm 1\%$ or better)
 - CFC-11 & CFC-12: Warner and Weiss, *Deep Sea Res. I*, 32:1485-1497, 1985
 - CFC-113: Bu and Warner, *Deep Sea Res. I*, 42:1151-1161, 1995
 - SF₆: Bullister, Wisegarver and Menzia, *Deep Sea Res. I*, 49:175-187, 2002

Pathway of Labrador Sea Water

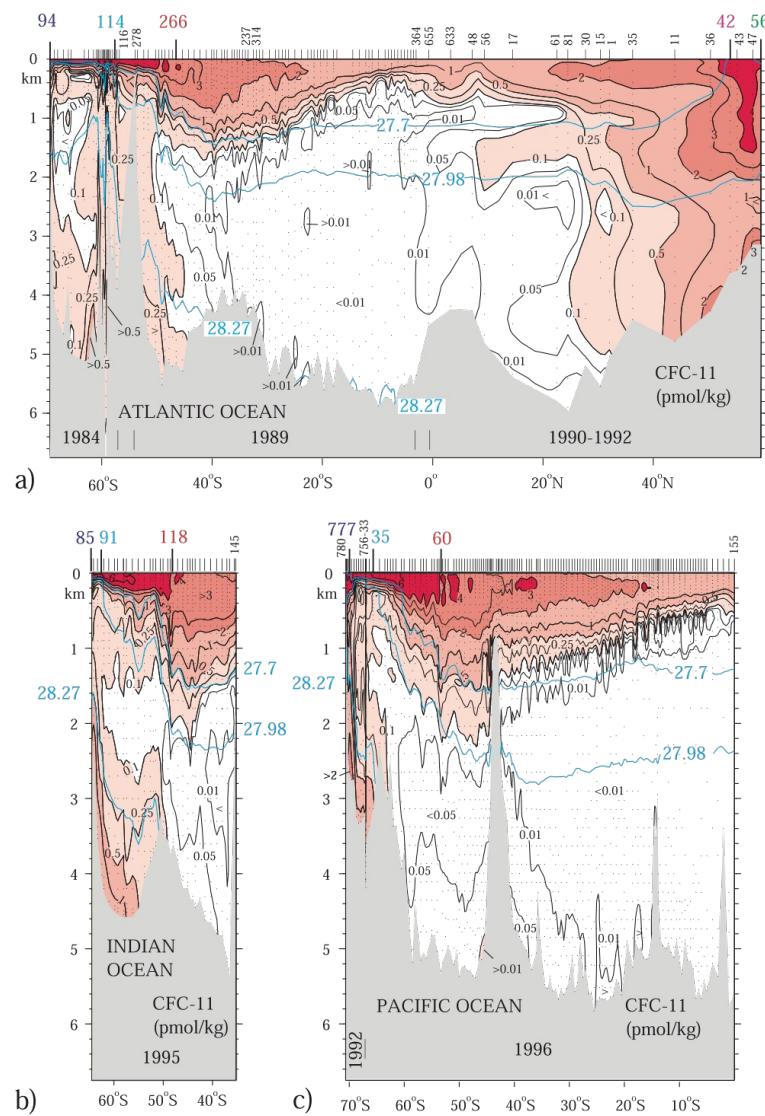

Rhein et al. (2002)

Four chlorofluorocarbon (CFC) sections taken at various times along 55°W south of the Grand Banks. Note the absence of any significant CFC signal at the depth of the Labrador Sea Water (about 1,500 meters depth) in 1983, but the sudden flooding of these depths with CFCs in the later sections, as newly formed Labrador Sea Water flows around the Grand Banks and into the Sargasso Sea. These changes correspond to the tritium increases seen in the Bermuda time series (see figure opposite).

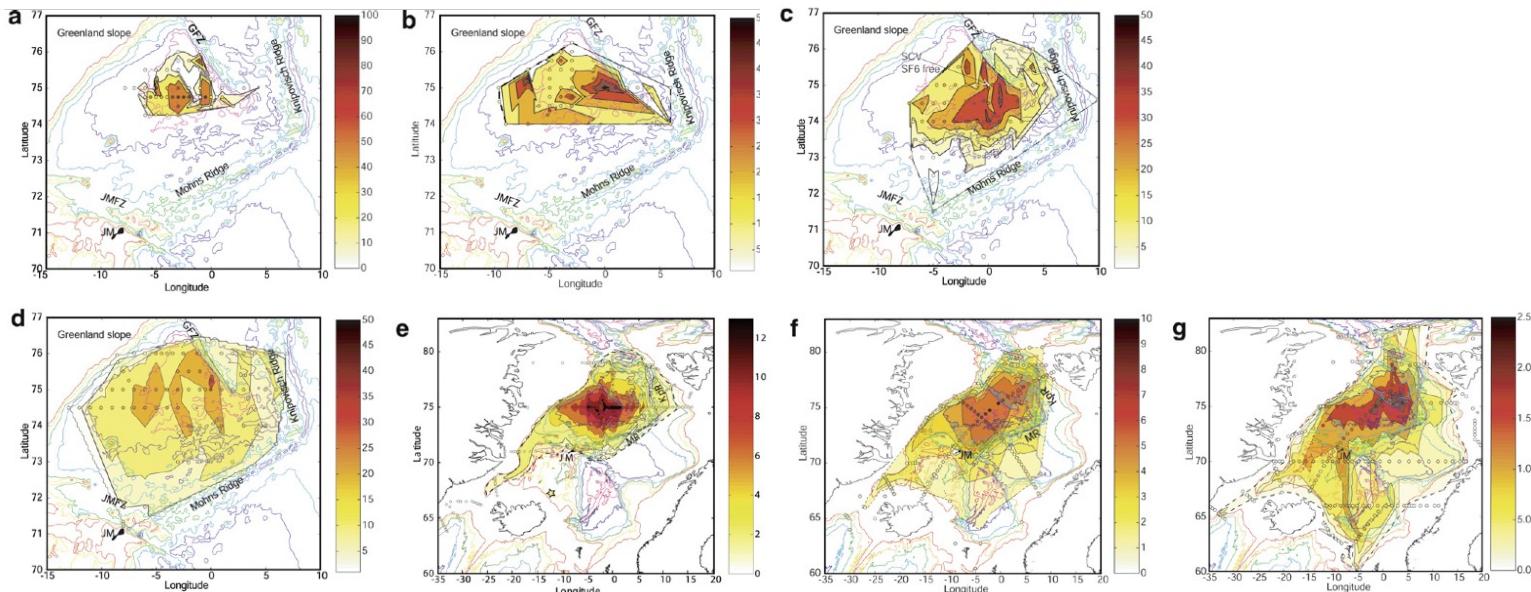

Fig. 10. Evolution of the SF₆ patch during the seven main subsequent cruises following the release. Triangle-based linear interpolation (Delaunay triangulation) contoured map of the Column Integral of SF₆ superimposed on colored bathymetry (black = 0 m, red = 1000 m, yellow = 1500 m, green = 2000 m, cyan = 2500 m, dark blue = 3000 m, magenta = 3500 m) from November/December 1996 (a), February/March 1997 (b), May 1997 (c), March 1998 (d), September 1998 where the star indicates the position of the profile shown in Fig. 11 (e), July 1999 (f) and June 2002 (g). Contours have been chosen to give a rough sketch of the distribution of the tracer. The dot at the station positions are colored according to the scale concentration for more details. Where there are dashed lines, the full extent of the tracer patch cannot be properly delineated from the survey coverage. The column integral for each station is given in units of nmol/m². The column integral includes the background concentration as well as the tracer from the release and therefore the tracer patch is defined as SF₆ concentrations >1 nmol/m² for all the cruises except June 2002. By June 2002 the SF₆ patch was well diluted and in order to obtain the true distribution of the SF₆ from the release, CFCs concentrations were used here to subtract the background SF₆. For the maps e-f-g, drawing of these contours has been guided so it does not interpolate over land.
