

Diagenesis - overview (with color code)

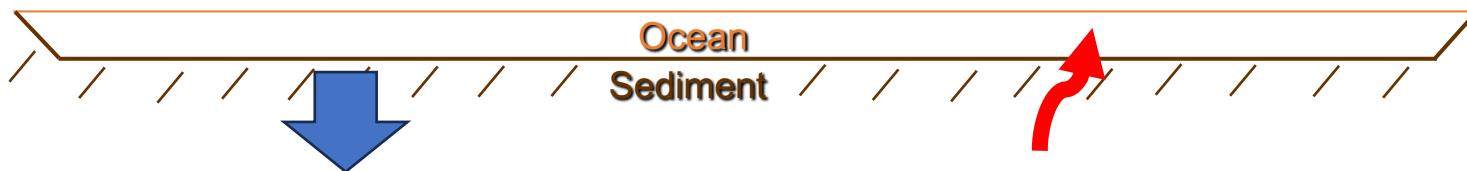

- Introduction to sediments & (early) diagenesis
- Organic matter degradation:
 - Redox control / zones
 - Sediment solute profiles: biogeochemical reactions & diffusive fluxes
 - Factors impacting sediment solute profiles / redox zones
 - Why do we care about diagenesis? Sediments as sources & sinks of nutrients and carbon

Diagenesis – learning objectives

- Why are sediments important, how do they differ from the water column?
- What is early diagenesis, what processes does it include, what is its impact on dissolved and solid species?
- What redox reactions (can) occur in marine sediments during organic matter degradation (in what sequence); what determines which reactions occur?
- What can sediment solute profiles tell us about reactions and fluxes in a sediment?

Why Study Sediments?

- Very large surface area of sediments with respect to the volume of seawater:

Vertical distance = 4 - 6 km

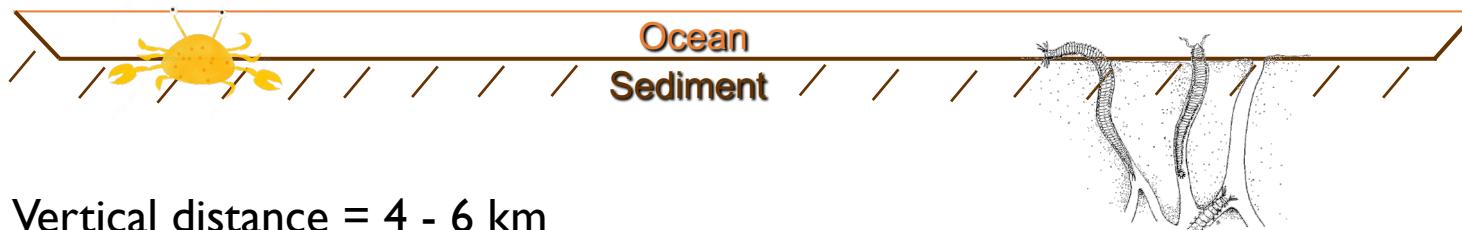

Horizontal distance = 1000's km

+ topographic features

- Large area of contact between seawater and sediment
- Strong potential for the two reservoirs to interact
- Geochemical balances of many elements depend on balance between **burial** and **remobilization**

Why Study Sediments?

- Very large surface area of sediments with respect to the volume of seawater:

Vertical distance = 4 - 6 km

Horizontal distance = 1000's km

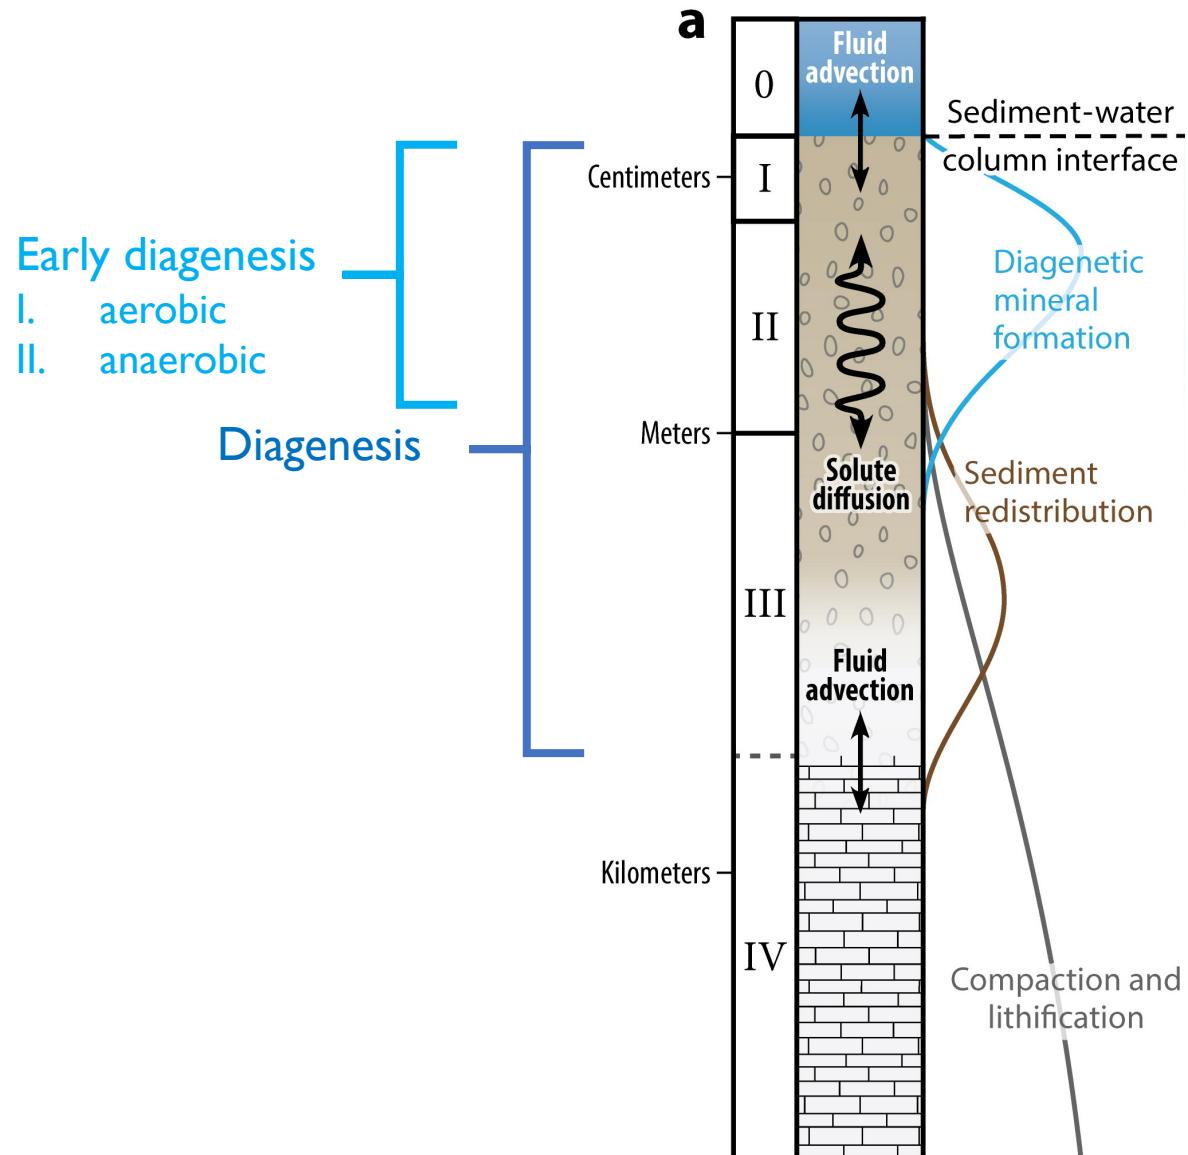

+ topographic features

- Large area of contact between seawater and sediment
- Strong potential for the two reservoirs to interact
- Geochemical balances of many elements depend on balance between burial and remobilization
- Surface sediments are habitat for a wide range of organisms

What is Diagenesis?

- Greek etymology:
 - dia* -- “passing through”
 - genesis* -- “origin, birth”
- Diagenesis is the “sum of all processes that change a sediment or sedimentary rock subsequent to its deposition from water, but excluding metamorphism and weathering” (Berner, 1980)
- Simply: “Reactions in Modern sediments...”

Reactions that occur at sediment depths shallower than a few 100 m (and < 50° C)

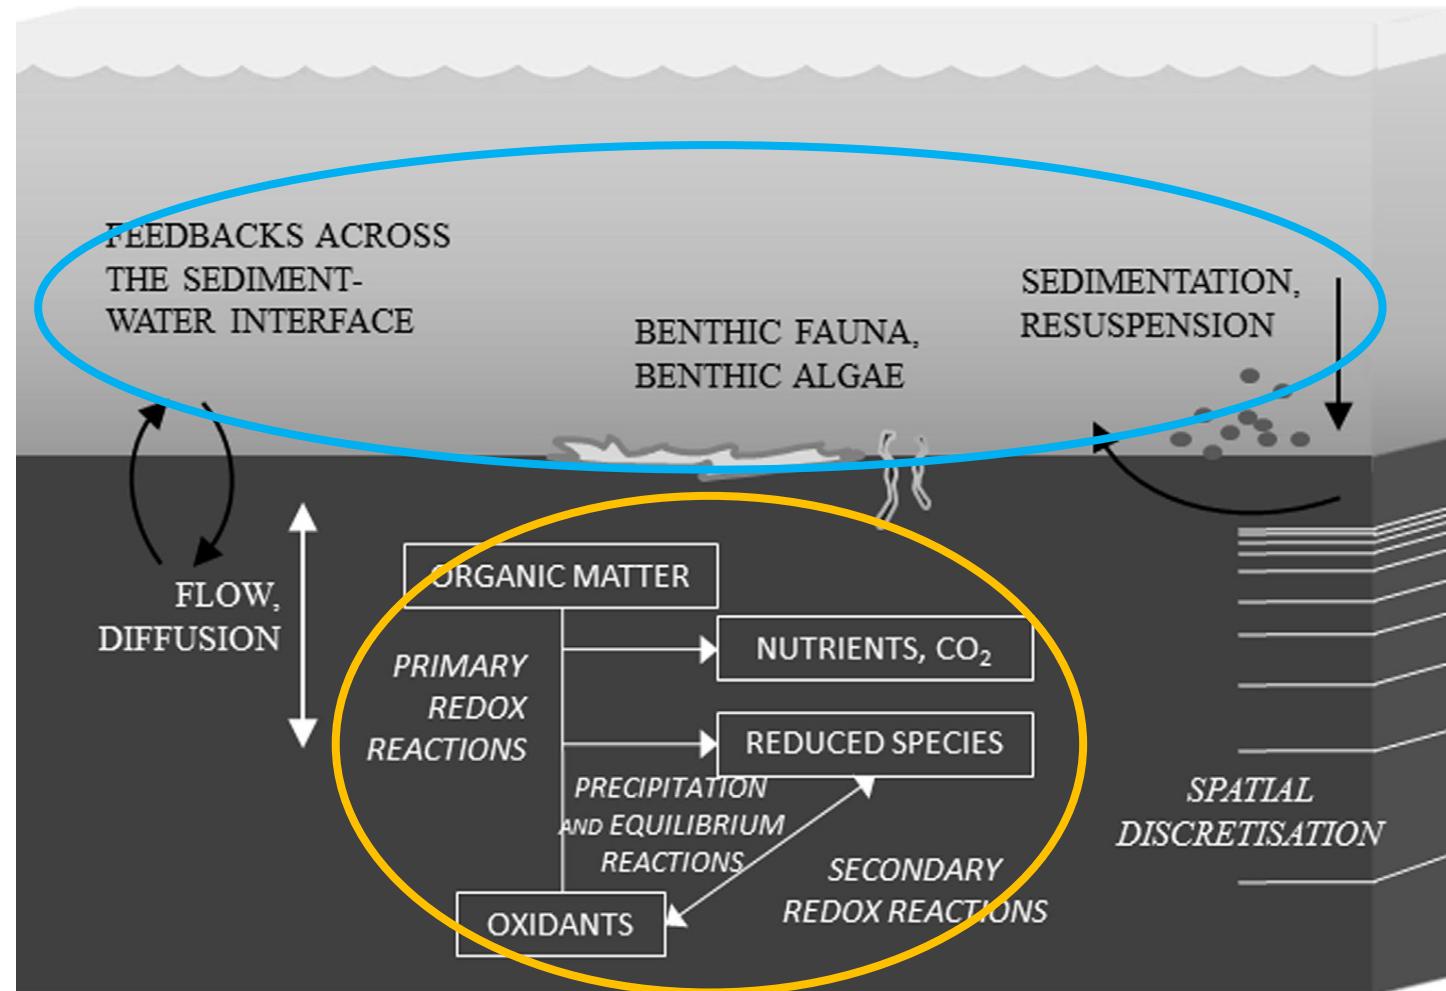

(Early) Diagenesis - Processes

(Biogeo-)Chemical reactions:

- Redox reactions
- Dissolution of solids
- Diffusion of dissolved species
- Precipitation of dissolved species

Biological / physical processes:

- Microbial activity
- Compaction
- Dewatering
- Bioturbation of solids
- Bioirrigation
- ...

Overall Result of (early) Diagenesis

Terrestrial debris (inorganic, organic)

+

Reactive marine organic matter / biogenic debris

Diagenetic
Reactions

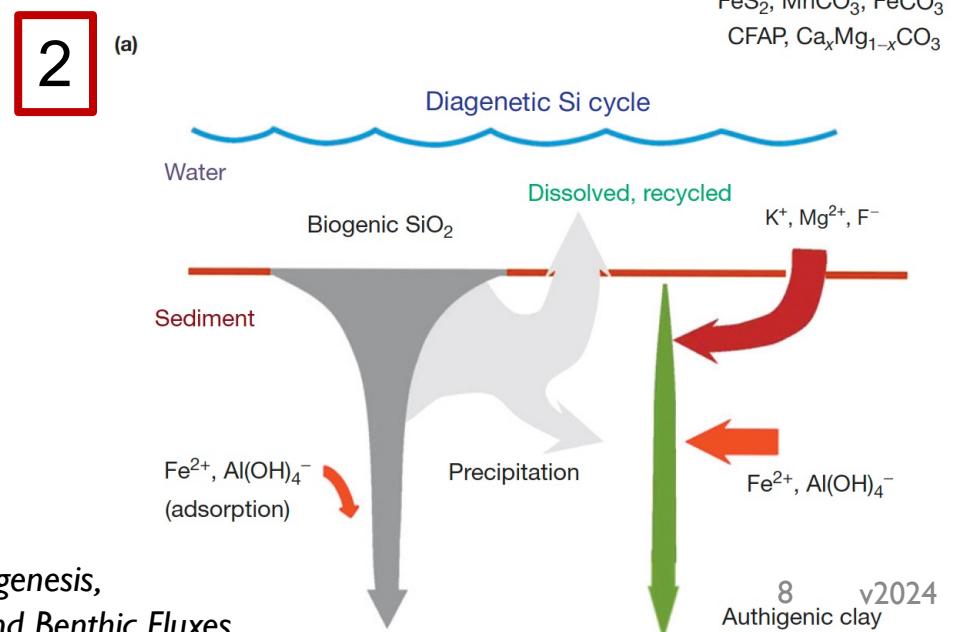

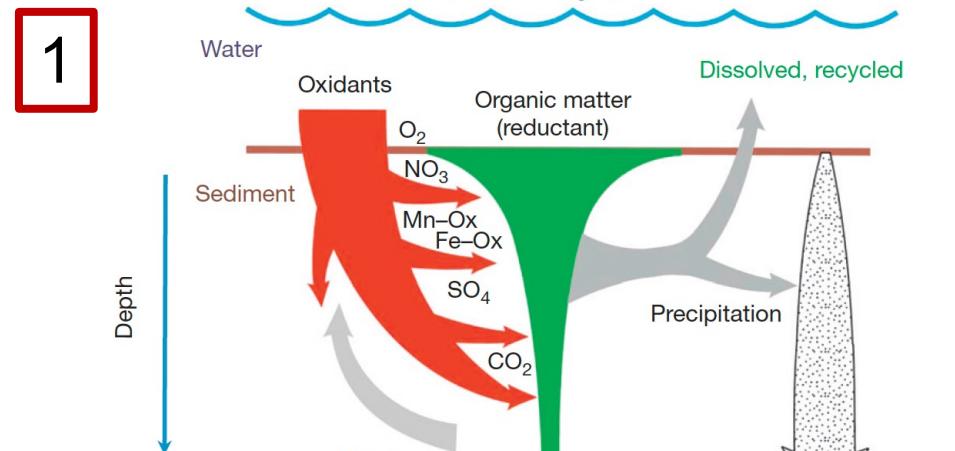

<i>Product</i>	<i>Fate</i>
Remineralized (inorganic) dissolved species (C, N, P, metals...)	Released, buried
Authigenic minerals (C, P, S, Si, Mn-Fe) (grow in place, not transported)	Buried
Residual OM	Buried

Early diagenesis: Biogeochemical reactions

Biogeochemical reactions during early diagenesis can be sorted into three groups* based on substrate:

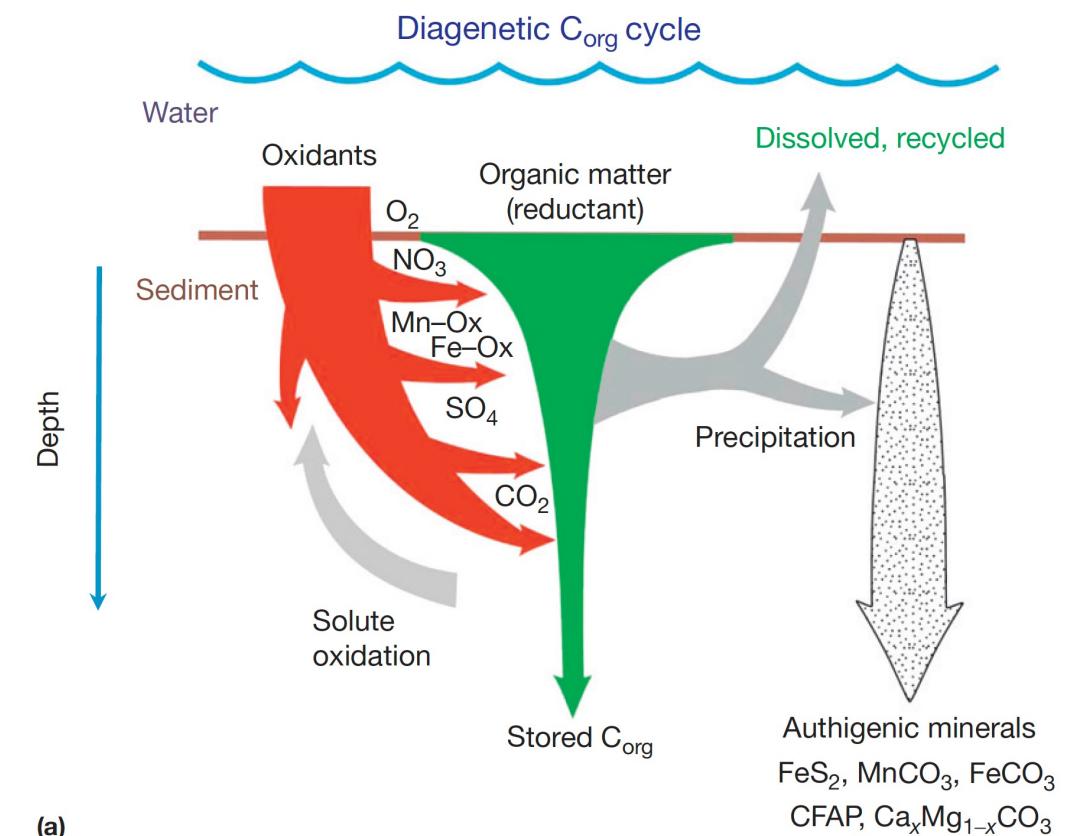

1. Related to organic matter degradation
2. Related to degradation of biogenic silica
- ‘reverse weathering’
3. Related to degradation (dissolution) of biogenic carbonate minerals

*that interact with each other

Organic matter degradation – redox controlled

- OM in sediments is thermodynamically unstable
- Decomposition occurs by various processes, each of which leads to **formation of specific species in solution and precipitation of authigenic minerals**
 - Involves series of reactions using **electron acceptors that are consumed sequentially**
 - Each successive reaction is **energetically less favorable**, and does not occur until the electron acceptor from the (previous) more favorable reaction has been mostly consumed

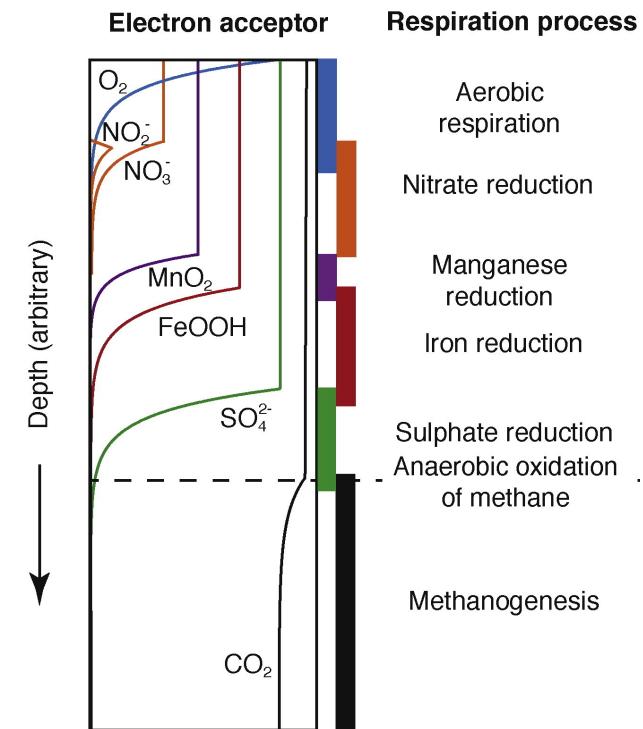

Organic matter degradation – redox zones

Table 1 The standard free energy of reaction, ΔG_r^0 , for the dominant environmental redox reactions

Reaction	$\Delta G_r^0 \text{ (kJ mol}^{-1}\text{) (half reaction)}$	$\Delta G_r^0 \text{ (kJ mol}^{-1}\text{)}$
Oxidation		
$\text{CH}_2\text{O}_{(aq)} + \text{H}_2\text{O} \rightarrow \text{CO}_{2(g)} + 4\text{H}^+ + 4\text{e}^-$	-27.4	
$\frac{2}{3}\text{CH}_3\text{OH}_{(aq)} + \frac{2}{3}\text{H}_2\text{O} \rightarrow \frac{2}{3}\text{CO}_{2(g)} + 4\text{H}^+ + 4\text{e}^-$	12.1	
$\frac{1}{2}\text{CH}_4_{(aq)} + \text{H}_2\text{O} \rightarrow \frac{1}{2}\text{CO}_{2(g)} + 4\text{H}^+ + 4\text{e}^-$	57.2	
Reduction		
$4\text{e}^- + 4\text{H}^+ + \text{O}_{2(aq)} \rightarrow 2\text{H}_2\text{O}$	-491.0	-518.4
$4\text{e}^- + 4.8\text{H}^+ + 0.8\text{NO}_3^-_{(aq)} \rightarrow 0.4\text{N}_{2(g)} + 2.4\text{H}_2\text{O}$	-480.2	-507.6
$4\text{e}^- + 8\text{H}^+ + 2\text{MnO}_{2(s)} \rightarrow 2\text{Mn}^{2+}_{(aq)} + 4\text{H}_2\text{O}$	-474.5	-501.9
$4\text{e}^- + 12\text{H}^+ + 2\text{FeOOH}_{(s)} \rightarrow 4\text{Fe}^{2+}_{(aq)} + 8\text{H}_2\text{O}$	-258.5	-285.9
$4\text{e}^- + 5\text{H}^+ + \frac{1}{2}\text{SO}_4^{2-}_{(aq)} \rightarrow \frac{1}{2}\text{H}_2\text{S}_{(aq)} + 2\text{H}_2\text{O}$	-116.0	-143.4
$4\text{e}^- + 4\text{H}^+ + \frac{1}{2}\text{CO}_{2(g)} \rightarrow \frac{1}{2}\text{CH}_4_{(aq)} + \text{H}_2\text{O}$	-57.2	-84.6

Sequence, i.e.,
one used up
after the other
(more or less)

Things to note:

- The amount of oxidant required to oxidise 1 mol of CH_2O differs
 - e.g., only 1 mol O_3^- but 2 moles of $\text{FeOOH} \rightarrow \text{FeOOH}$ is used up twice as fast
- Redox reactions are generally catalysed by different bacteria or archaea that use this for energy

Organic matter degradation – redox zones

Overall reaction:

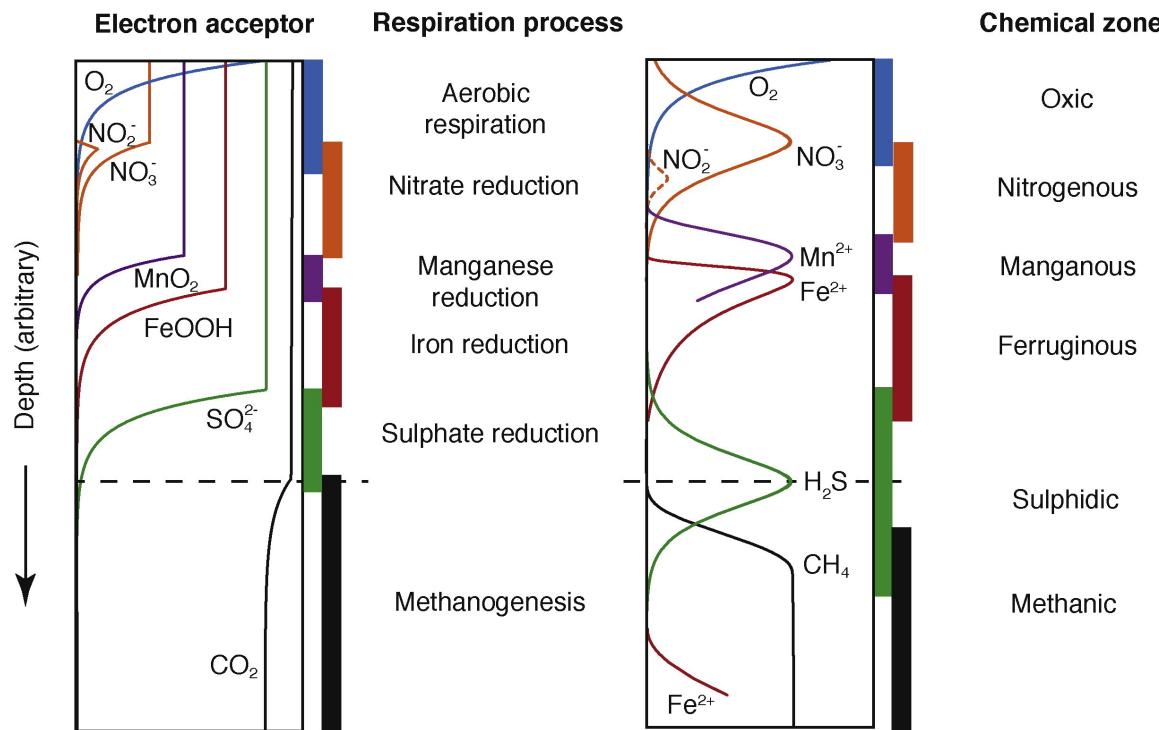

- Combining oxidation half-reaction (i.e., oxidation of CH_2O to CO_2) with reduction half-reaction
- Account for nutrients in organic material (i.e., NH_3 , H_3PO_4) that are released as OM is oxidised

Table 3 Overall stoichiometric (C/N/P) organic matter oxidation reactions. Model Redfield ratios for x , y , and z are typically taken as 106, 16, and 1

Metabolic redox process	Overall reaction
Aerobic respiration	$(\text{CH}_2\text{O})_x(\text{NH}_3)_y(\text{H}_3\text{PO}_4)_z + (x+2y)\text{O}_2 \rightarrow x\text{CO}_2 + (x+y)\text{H}_2\text{O} + y\text{HNO}_3 + z\text{H}_3\text{PO}_4$
Nitrate reduction	$5(\text{CH}_2\text{O})_x(\text{NH}_3)_y(\text{H}_3\text{PO}_4)_z + 4x\text{NO}_3^- \rightarrow x\text{CO}_2 + 3x\text{H}_2\text{O} + 4x\text{HCO}_3^- + 2x\text{N}_2 + 5y\text{NH}_3 + 5z\text{H}_3\text{PO}_4$
Manganese reduction	$(\text{CH}_2\text{O})_x(\text{NH}_3)_y(\text{H}_3\text{PO}_4)_z + 2x\text{MnO}_2(\text{s}) + 3x\text{CO}_2 + x\text{H}_2\text{O} \rightarrow 2x\text{Mn}^{2+} + 4x\text{HCO}_3^- + y\text{NH}_3 + z\text{H}_3\text{PO}_4$
Iron reduction	$(\text{CH}_2\text{O})_x(\text{NH}_3)_y(\text{H}_3\text{PO}_4)_z + 4x\text{Fe(OH)}_3 + 7x\text{CO}_2 \rightarrow 4x\text{Fe}^{2+} + 8x\text{HCO}_3^- + 3x\text{H}_2\text{O} + y\text{NH}_3 + z\text{H}_3\text{PO}_4$
Sulfate reduction	$2(\text{CH}_2\text{O})_x(\text{NH}_3)_y(\text{H}_3\text{PO}_4)_z + x\text{SO}_4^{2-} \rightarrow x\text{H}_2\text{S} + 2x\text{HCO}_3^- + 2y\text{NH}_3 + 2z\text{H}_3\text{PO}_4$
Methane production	$(\text{CH}_2\text{O})_x(\text{NH}_3)_y(\text{H}_3\text{PO}_4)_z \rightarrow \frac{x}{2}\text{CH}_4 + \frac{x}{2}\text{CO}_2 + y\text{NH}_3 + z\text{H}_3\text{PO}_4$

All organic matter degradation (aerobic or anaerobic) release nutrients (NH_3 , HPO_4^{2-})!

OM degradation – solute profiles

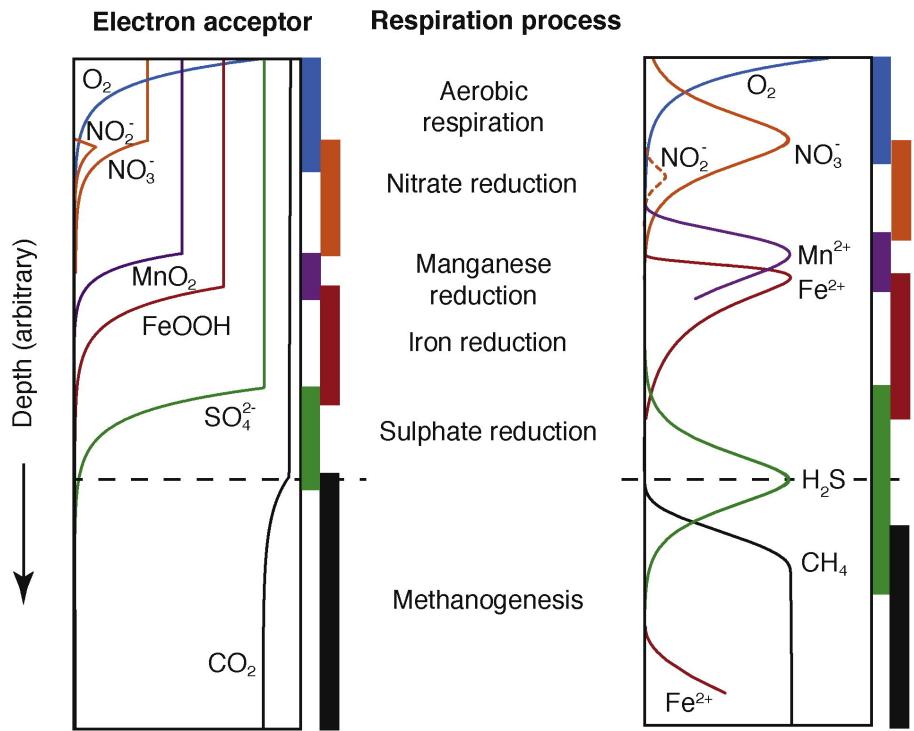

Roberts 2015, Earth-Science Reviews

Redox zones can be identified by the dissolved species their dominant reactions release to (Mn^{2+} , Fe^{2+} , H_2S , CH_4) or taken up from (O_2 , NO_3^- , SO_4^{2-}) sediment porewaters.

Need to also account for removal via precipitation & diffusion.

OM degradation – solute profiles

Roberts 2015, Earth-Science Reviews

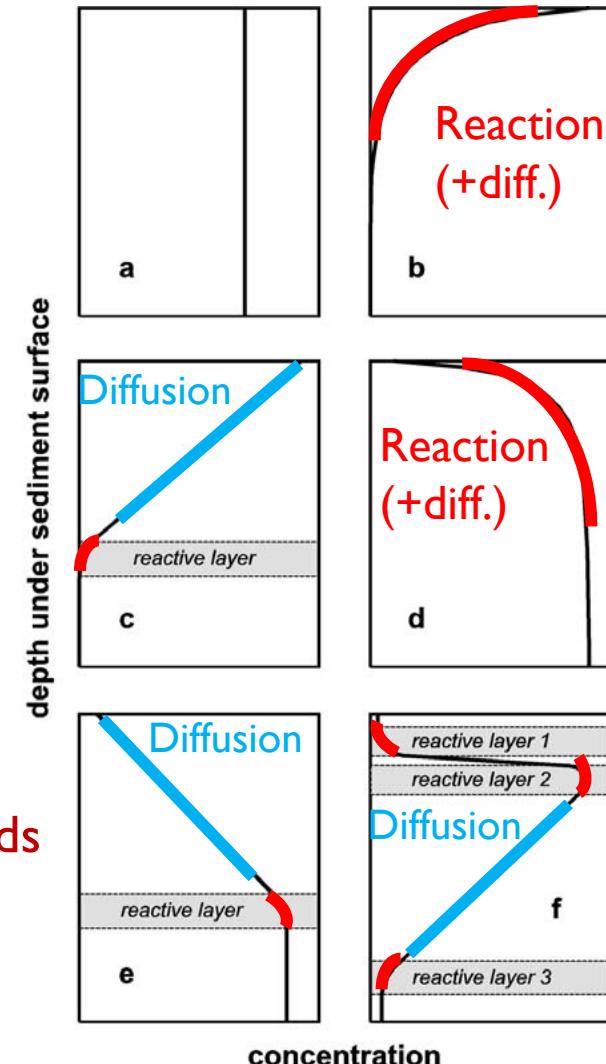

Redox zones can be identified by the dissolved species their dominant reactions release to (Mn^{2+} , Fe^{2+} , H_2S , CH_4) or taken up from (O_2 , NO_3^- , SO_4^{2-}) sediment porewaters.

Need to also account for removal via precipitation & diffusion.

Interpreting sediment solute profiles:

- No reaction (e.g., Cl^-)
- Removal in upper sediment (e.g., O_2)
- Removal in specific layer (e.g., SO_4^{2-})
- Production in upper sediment (e.g., silica)
- Production in specific layer
- Production in one layer (2), removal in two other (1,3; e.g., NO_3^- , Fe^{2+} , Mn^{2+})

Shape of solute profile depends on the reaction(s) a solute is involved in and diffusion*

*technically only applicable to fine grain sediments (no advection) without any disturbance by bioturbation or physical processes 13

Calculating fluxes from steady state solute profiles

Diffusive flux of solute i:

$$J_{\text{sed},i} = -D_{\text{sed},i} \varphi \frac{\partial C_i}{\partial z}$$

$D_{\text{sed},i}$ diffusion coefficient of i within sediment

φ porosity

$\frac{\partial C_i}{\partial z}$ concentration gradient of i in sediment

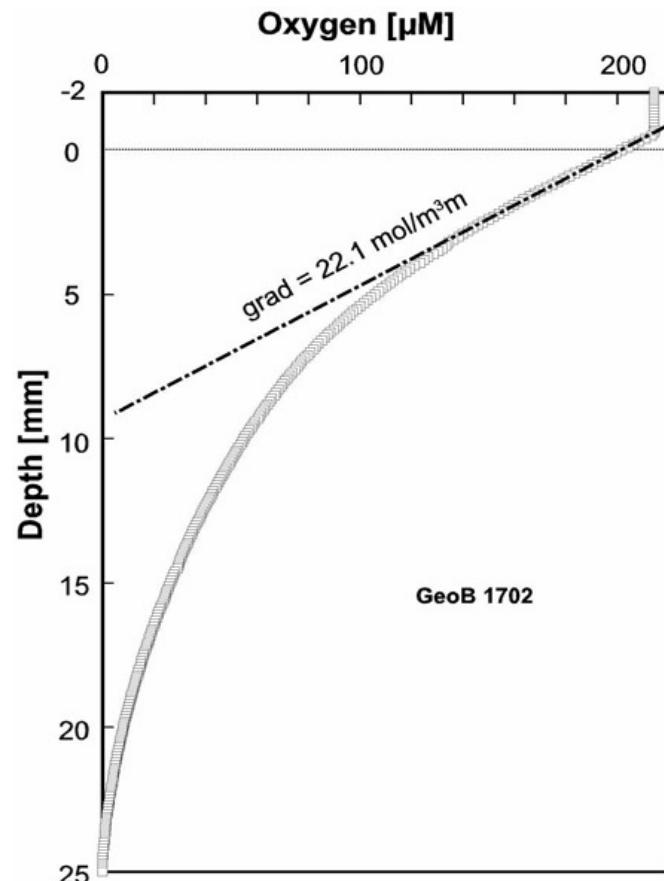

Diffusivity of solute i within in sediment*:

$$D_{\text{sed},i} = D_{\text{sw},i} \varphi^2$$

$D_{\text{sw},i}$ diffusion coefficient of solute i in seawater

*this is just one way to calculate D_{sed} ; there are other parametrisations

Example: O_2 flux into sediment:

$$J_{\text{sed}} = ???$$

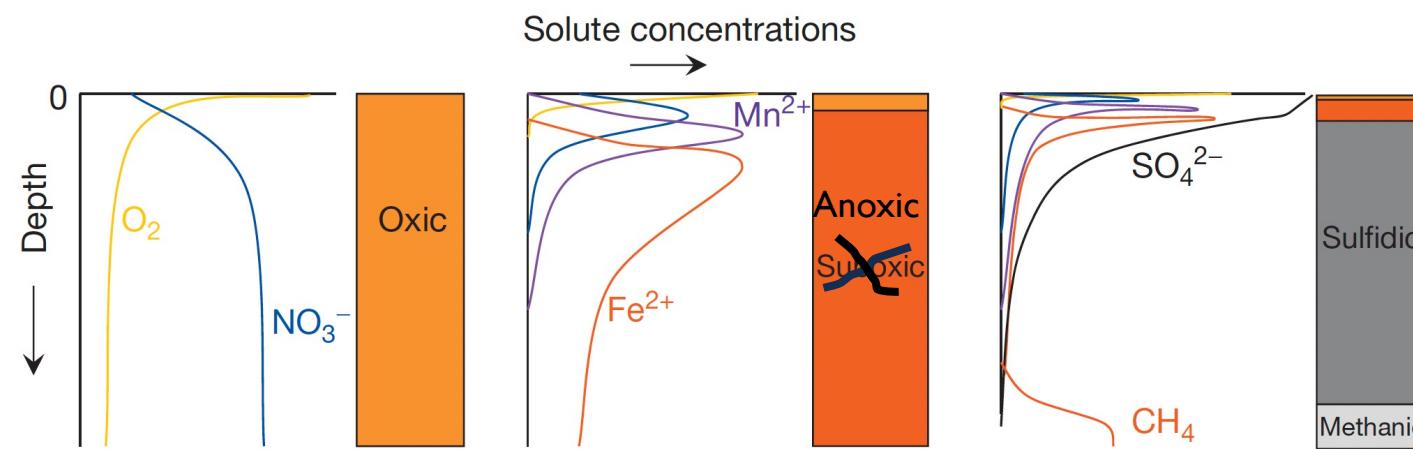

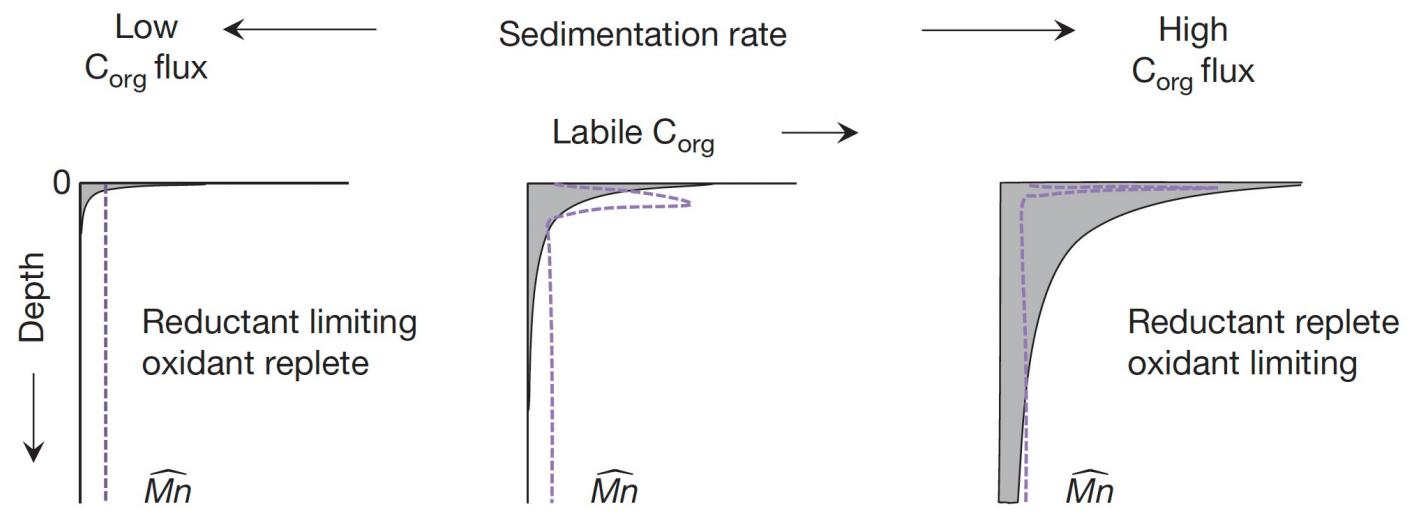

$$\varphi = 0.8$$

$$D_{\text{sw}} (\text{at } 5^\circ\text{C}) = 1.23 \cdot 10^{-9} \text{ m}^2\text{s}^{-1}$$

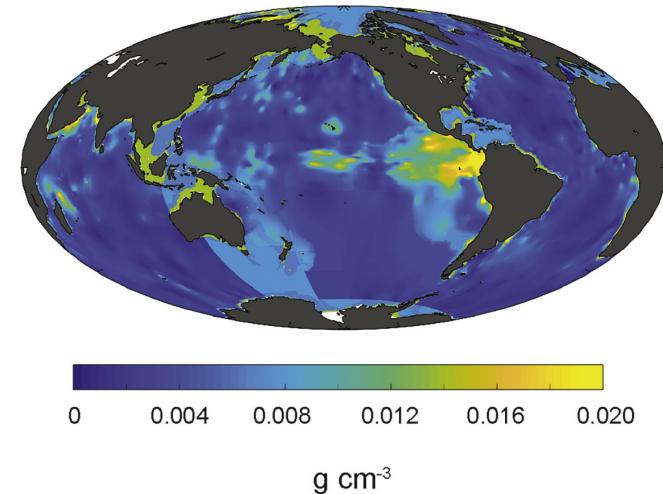

What determines redox zones/solute profiles?

- Availability (and quality?) of reductant (organic matter)
 - organic matter supply / sedimentation rate
- Availability of oxidant(s)
 - Sediment type (biogenic, lithogenic...)
 - Bottom water oxygen
- Physical characteristics & processes
 - porosity, permeability, ...
 - sediment resuspension, ...
- Presence of macrofauna
 - Bioturbation & irrigation

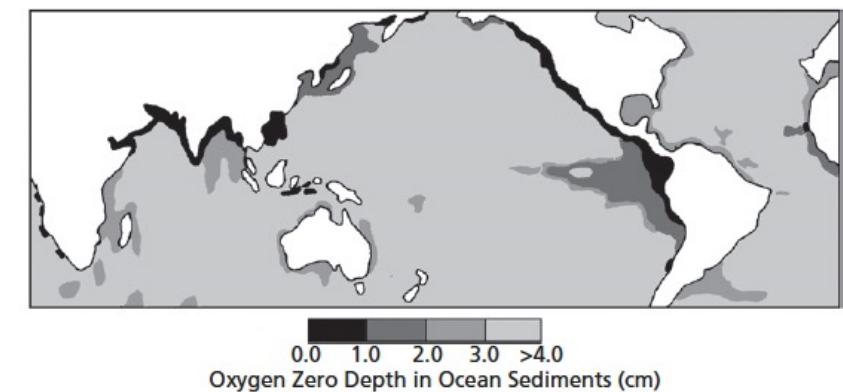

Reductant (organic carbon) supply

Concentration of particular organic carbon (POC) at the sea floor:

LaRowe et al. 2020, *Earth Sci. Rev.*

Sediment type – classifications (review)

- Origin of particles (i.e., how/where they were formed)

- **biogenous (biogenic)**: produced by living organisms
- **lithogenous (lithogenic)**: produced from weathering
 - also: **terrigenous**: produced on land, **detrital**
- **hydrogenous**: formed by reactions in water
 - similar: **authigenic**: produced in situ (i.e., in sediments)
- **cosmogenous**: produced from extraterrestrial sources
- ...

- Grain size

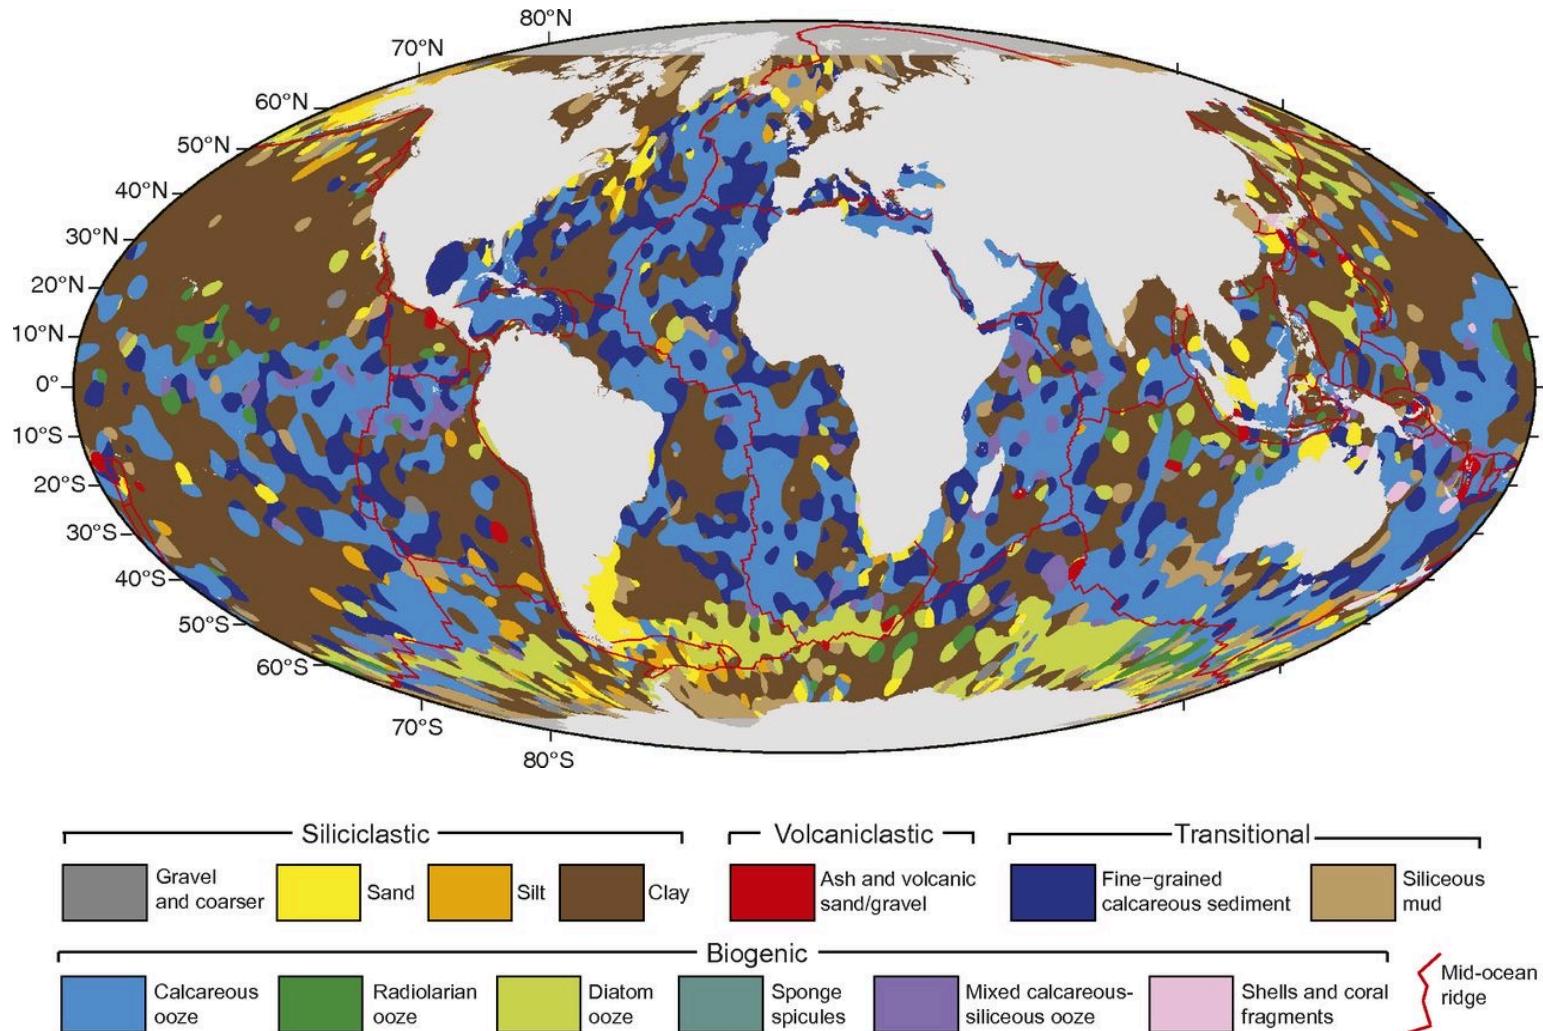

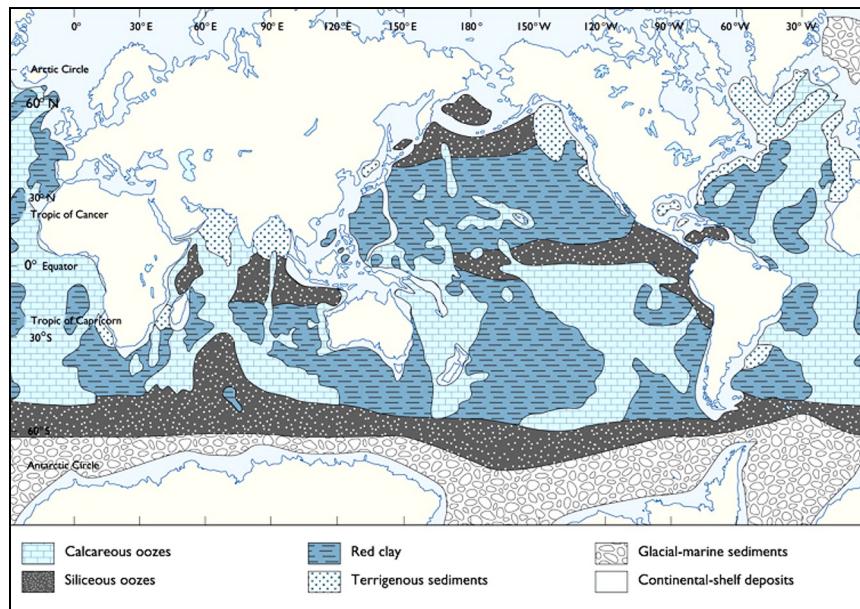

- gravel, sand, silt, clay

- Location/depth relative to land

- Shelf, slope, deep ocean (pelagic) sediments, ...

- ...

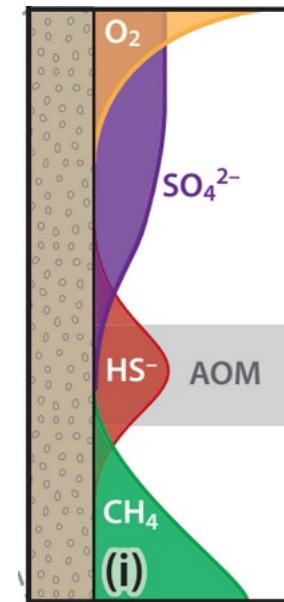

Sediment types – where are they found?

Sediment types – impact on OM degradation?

■ Geochemistry

- e.g., biogenic (carbonates, opal) vs. lithogenic sediments
- mineralogy (e.g., type of aluminosilicates)
- ...

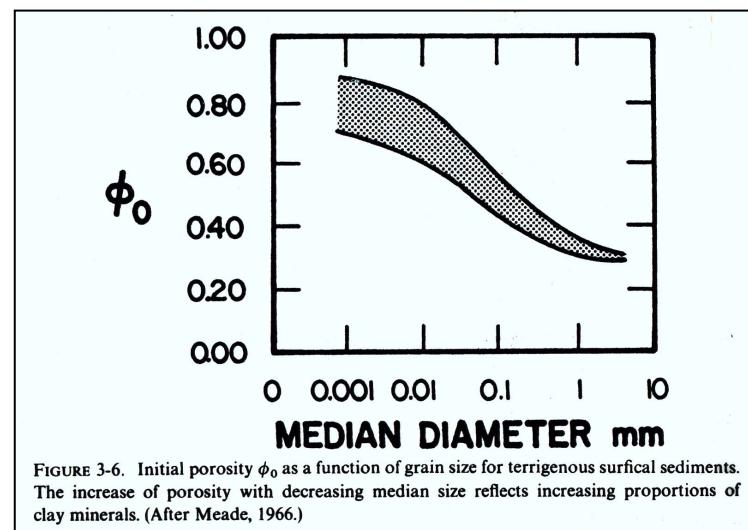

Organic matter degradation in carbonate sediments

Fantle et al 2020,
Ann. Rev. Earth. Plan. Sci.

■ Grain size (clay < silt < sand) impacts:

- Porosity
 - clay (~0.8) > silt (~0.6) > sand (~0.5)
- Permeability:
 - sand > silt > clay
- Surface area
 - clay > silt > sand

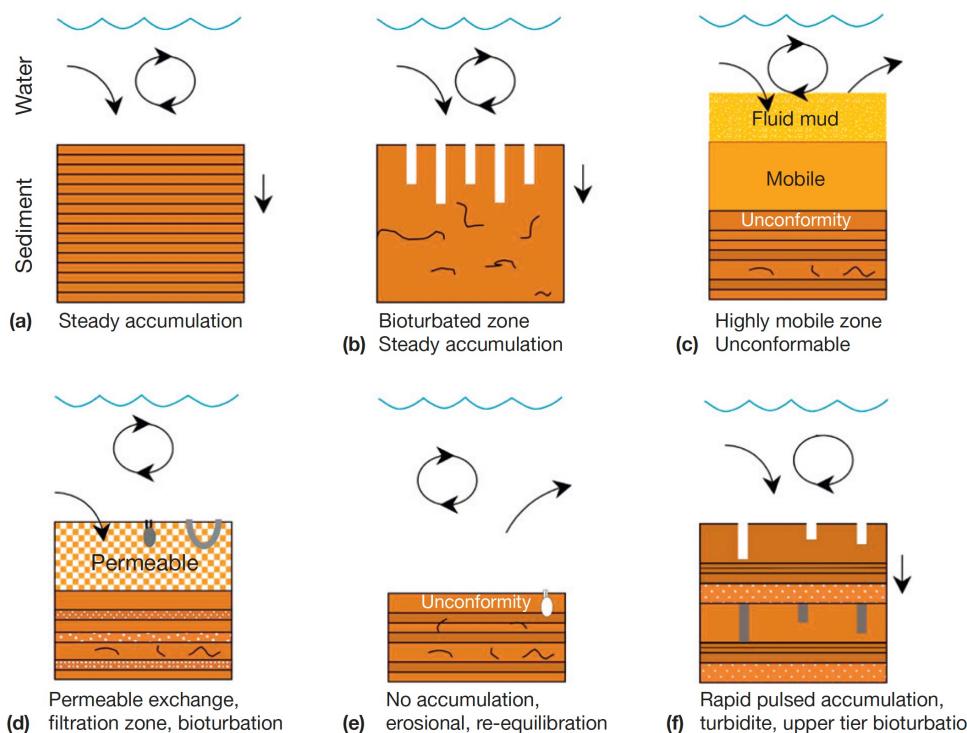

(Bio-)physical processes

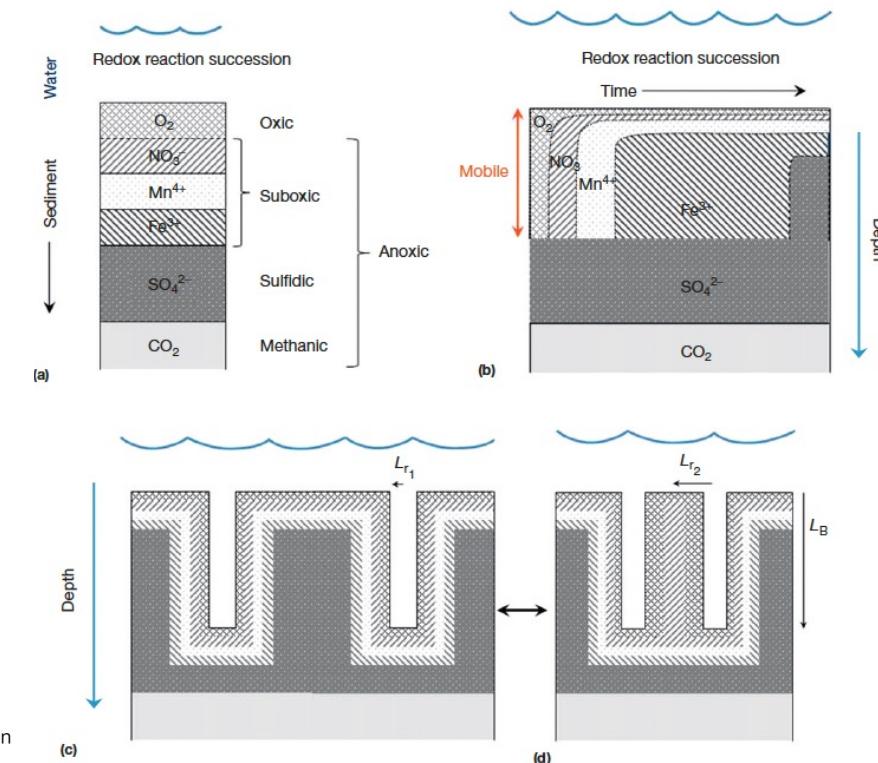

Reoxygenation
and/or sediment
mixing thanks to:

- Bioturbation/-irrigation by macrofauna
 - left: b, f, g
 - right: c,d
- Sediment resuspension in mobile layer (via waves, etc.)
 - left: c,
 - right: b
- Advection through permeable (sandy) layers
 - left: d

Processes:

Effect on redox zonation:

Bioturbation / Bioirrigation

aRPD = apparent redox potential discontinuity

Why do we care about diagenesis?

From a marine chemistry perspective:

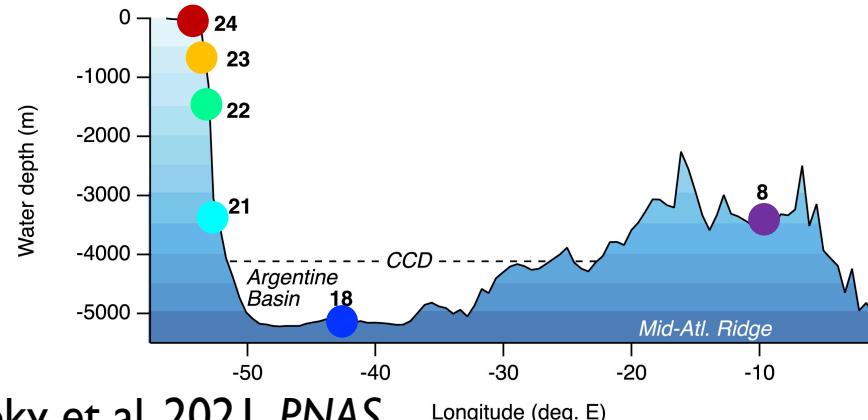

- Solute exchange:
 - source or sink of nutrients (NO_3 , NH_3 , PO_4 , Fe, other micronutrients)
 - source or sink of pollutants (e.g., heavy metals, As)
 - source of greenhouse gases (CO_2 , N_2O , CH_4)
- Burial vs. remineralization of organic matter
 - sequestration of carbon
- ...

Sediment sources & sinks – macronutrients O₂ & Fe

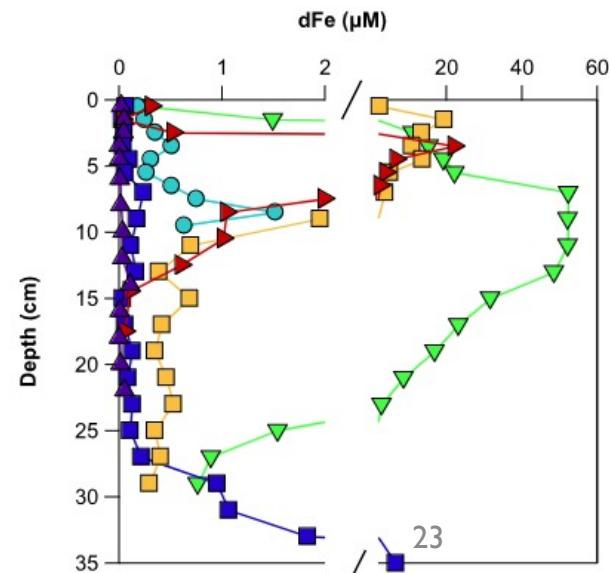

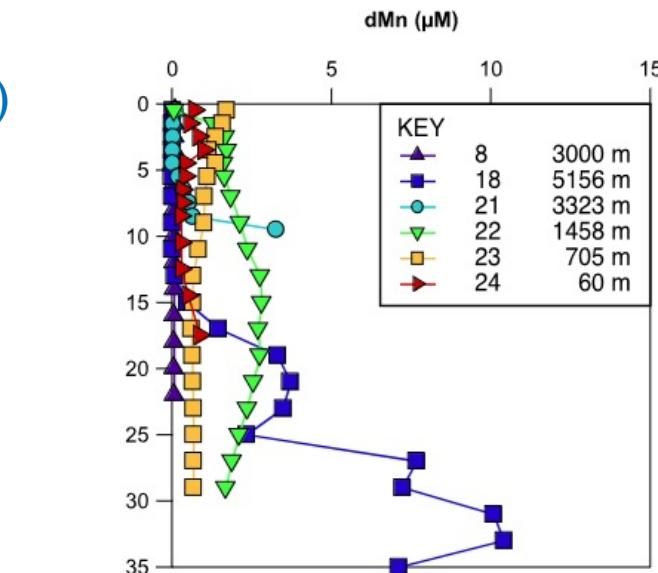

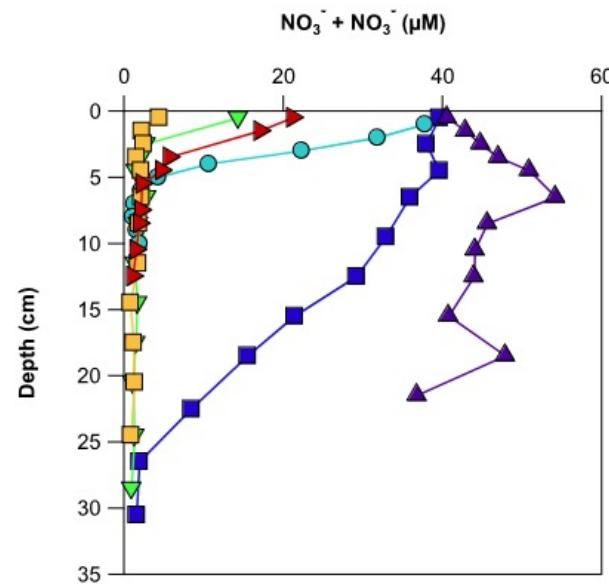

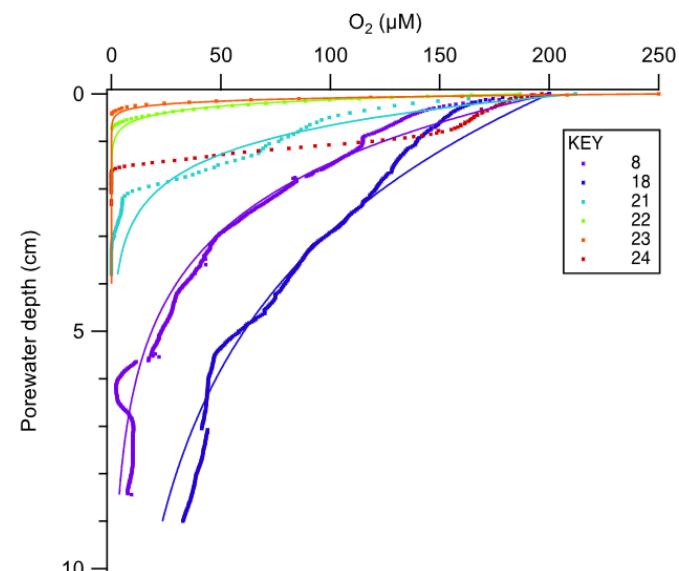

Are sediments a source or sink of:

- Oxygen?
- Nitrogen?
- Fe, Mn?
- Phosphorus?

Examples profiles (southwest Atlantic; east of Uruguay)

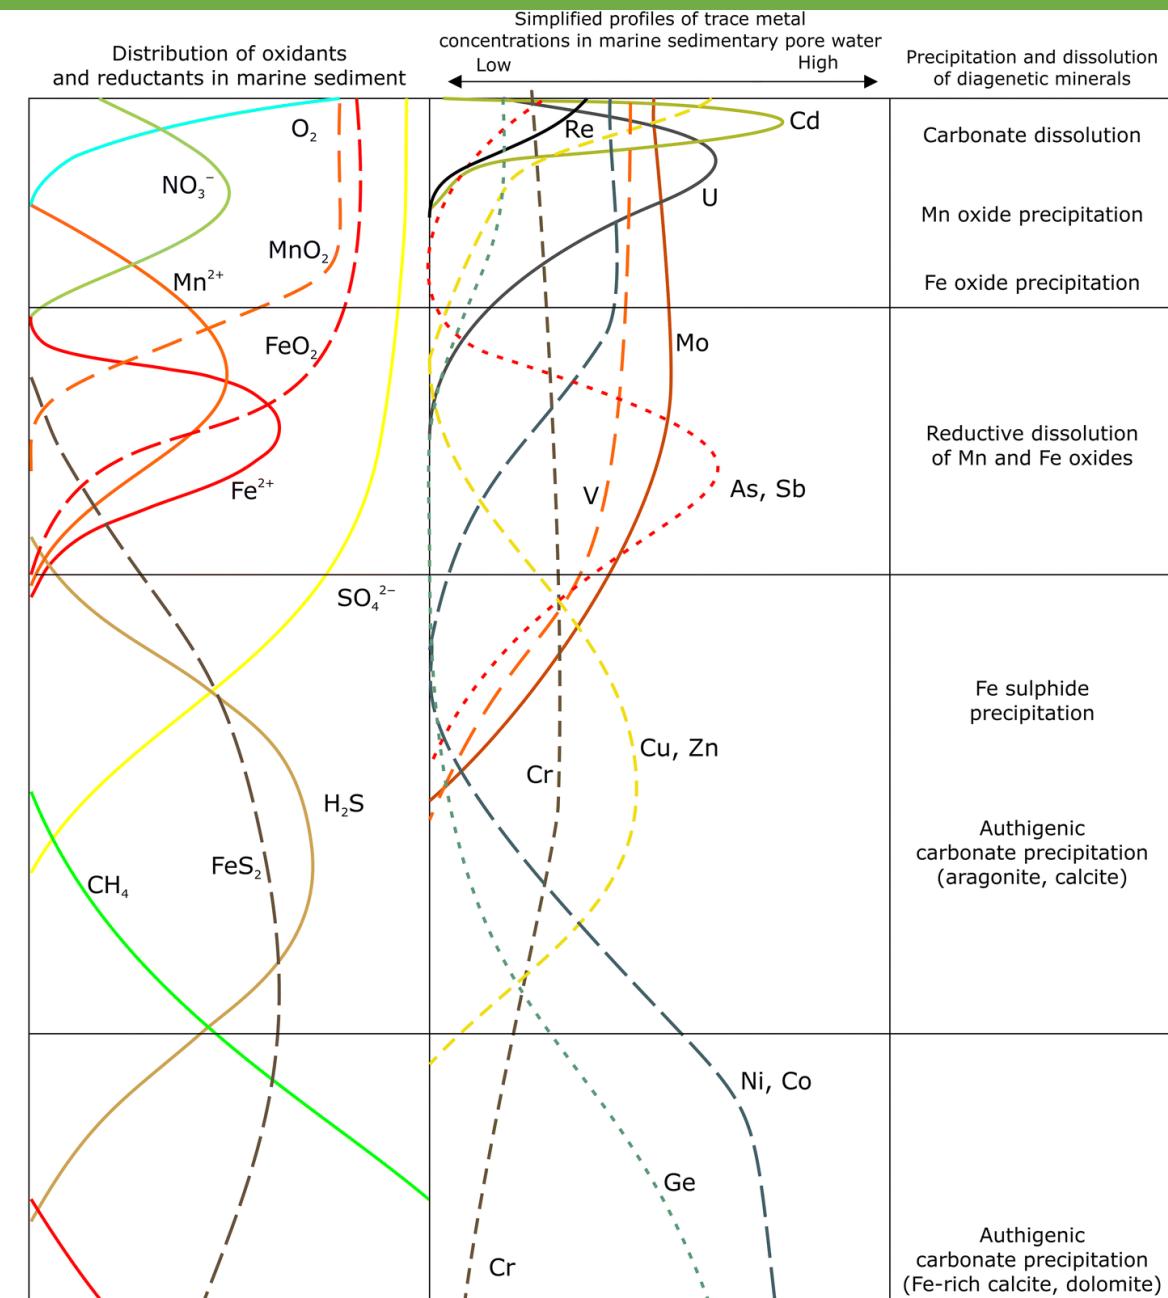

Homoky et al. 2021, PNAS

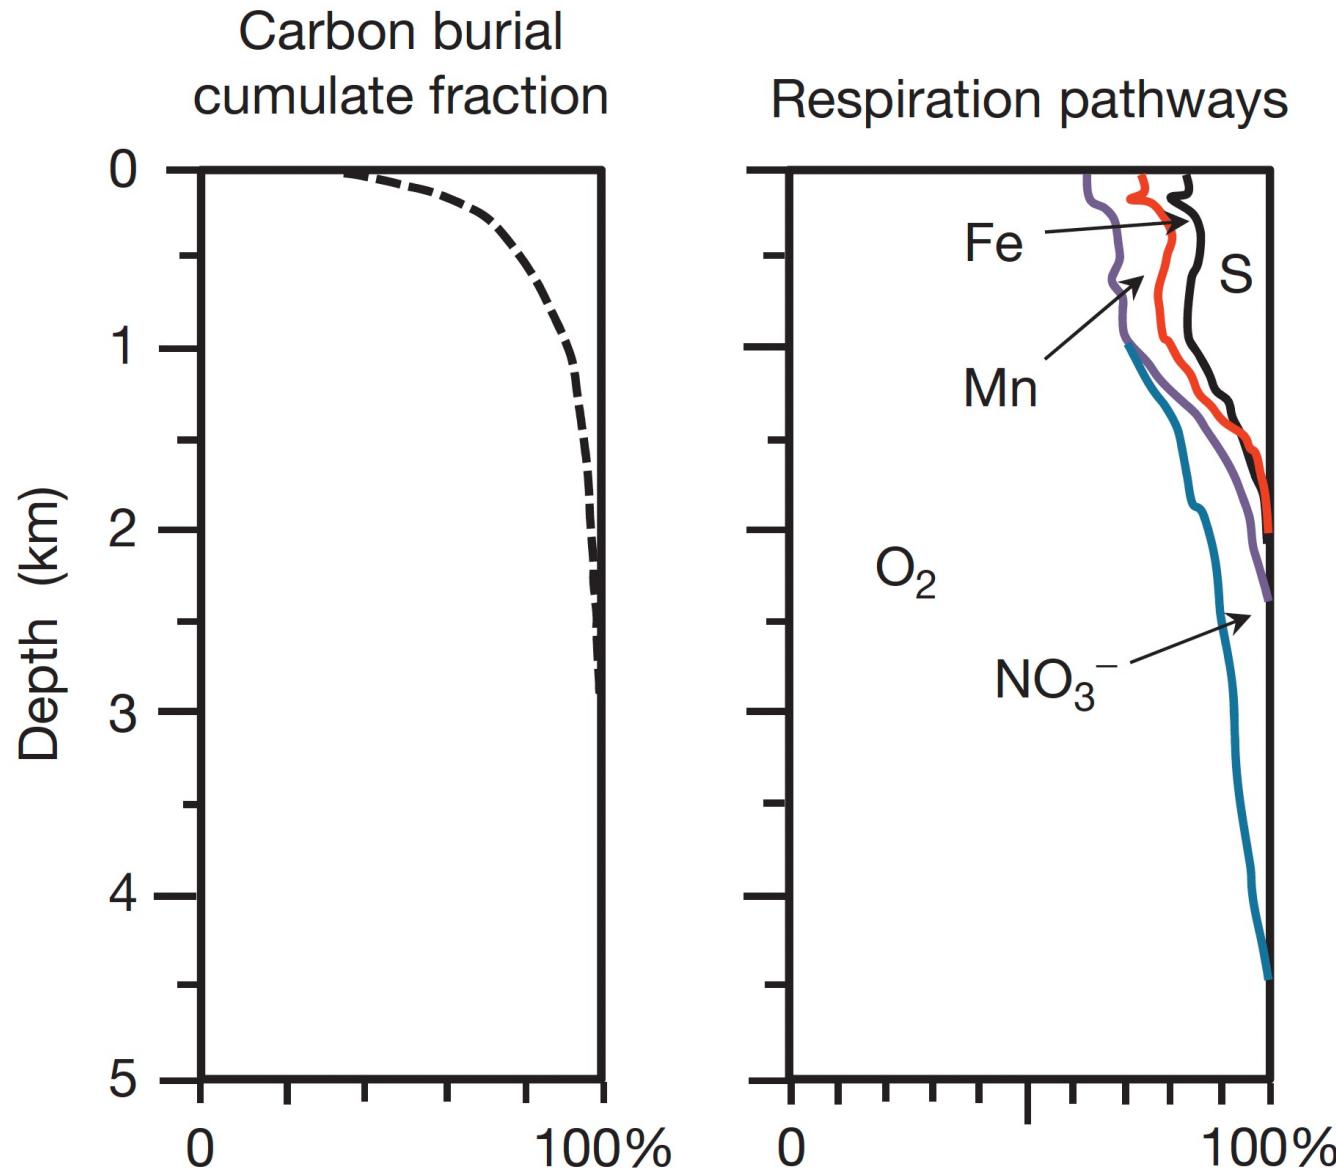

Sediment sources & sinks – micronutrients / pollutants

- Trace elements can be nutrients (e.g., Co, Zn) or pollutants (e.g., Cd, As) or both (e.g., Cu)
- Some trace metals are associated with certain solid phases (e.g., Mn, Fe oxides) and are removed or released when those precipitate / dissolve
- Some trace metals get reduced themselves in more reductive layers and may become more/less soluble (or toxic)

Carbon respiration & burial – where and why?

- 90% of organic carbon is respired in the water column and only ~1% or less ends up buried in sediments (i.e. not respiration in sediments)
- Majority of organic carbon is buried (but also respiration) in relatively shallow regions (near coasts)
- Oxic respiration most important pathway

Table 14.1 Ocean Organic Carbon Burial 10^{12} g organic C yr⁻¹. Based on Burdige (2007).

Depth Range (km)	% ocean area	Organic Carbon Burial (% of total in brackets)
0–0.2	7	152 (50%)
0.2–2	9	96 (31%)
>2	84	61 (20%)

Carbon preservation – factors

■ Recalcitrance of OM (i.e., undegradable substrate)?

- Protection by mineral surfaces?
 - positive correlation of OM preservation & surface area
- Association with Fe, Mn

■ Oxidant availability?

■ Oxygen exposure time?

- Sedimentation rate
- Bottom water oxygen
- (Bio-)physical reworking

■ ...

The balance between degradation and preservation of sedimentary organic carbon (OC) is important for global carbon and oxygen cycles¹. The relative importance of different mechanisms and environmental conditions contributing to marine sedimentary OC preservation, however, remains unclear^{2–8}. Simple organic molecules can be geopolymersized into recalcitrant forms by means of the Maillard reaction⁹, although reaction kinetics at marine sedimentary temperatures are thought to be

Carbon preservation – factors

“reactivity of organic matter is determined by the interaction between the compound and its ecosystem, not just the chemical nature of the organic compounds” – LaRowe et al. 2020, *Earth Sci. Rev.*
